Status Præsens.—October 24: The baby lies with its right index finger in its mouth. Occasionally cries, but cries at once on being disturbed. Is of fair size; weighs 15 pounds. The head is square; anterior fontanelle 38x34 mm.; soft blowing systolic murmur over it. The scalp is sweating slightly.

The right eye is prominent. The upper lid is slightly swollen and shows a pale blue oval discoloration at the upper margin. The left upper eyelid, which was closed yesterday and bright red, is less swollen; pale red; the skin finely wrinkled. The lids open one-eighth inch. The bulbs move naturally; both are very prominent and seem to look down. The conjunctiva is normal.

The rest of the face is slightly puffy, the cheeks flushed, ears pale. There is a scanty eruption of minute red papules in the scalp and on the abdomen, but no pectehiæ.

The lower central incisors are about half way through. The gum around them is slightly swollen, reddish purple, the purple most marked close to the teeth. The upper incisors can not be seen. The gum over them is swollen, forming two oblong oval elevations, the right 1 cm., the left 1.5 cm. long. These are dirty red at the bases, blue at the tops, but the extreme tops are broken and appear as ragged dirty-looking ulcers covered with small granulations. The mucosa of the rest of the mouth and pharynx is healthy looking; the tongue is not swollen; has a very thin white coat.

The thorax is of good size. The sternum and costal cartilages are flat and look as if pushed in, forming a ridge running from the nipples to the flanks, parallel to the margin of the ribs, from which the ridge is separated by a shallow groove. The chondrocostal articulations are firm; very slightly swollen. Heart and lungs negative.

The abdomen is below the level of the ribs. Liver and spleen not enlarged. The back is tender, but otherwise negative.

The left arm lies extended; the right thumb is in the mouth and can be moved away without evidences of great tenderness. The wrists and lower fourths of the forearms are swollen; the skin is not tense, but there is a firm swelling seemingly beneath the deep fascia. The hands are emaciated. The thighs and knees are negative. The upper parts of the tibiae are not distinctly thickened. The lower thirds of the legs and the ankles are swollen, the skin glossy, and at the same time pitted, like an orange peel, with slight bluish yellow discoloration. The swelling is very firm. Touching the arms and legs causes severe crying, with many tears. The legs and feet are kept extended; no effort is made to move them.

Blood: Reds, 4,000,000; leucocytes, 11,700; hgm., 80 per cent. Differential count (Dr. H. A. Freund): Small lymphocytes, 14.2 per cent.; large lymphocytes, 9 per cent.; polymorphous, 75.2 per cent.; transitional, 0.8 per cent.; eosinophile, 0.4 per cent.; basophile, 0.4 per cent. Few microcytes; many macrocytes; few poikilocytes.

Treatment and Course.—Orange juice was begun as soon as the baby was admitted. It took one ounce of a 25 per cent. mixture very well, apparently liking it, before each feeding. It also took the following milk mixture: Cream, 8 fluid ounces; milk, 1½ fluid ounces; lime water, 1 fluid ounce; water, 9½ fluid ounces; milk sugar, 6¼ drams. Heated at 99.5 C. for twenty minutes; then cooled; 5 ounces every three hours.

October 25: The baby is distinctly better. It looks more intelligent and does not cry as much as before. The swelling is entirely gone from the left eye. The blue spot on the right lid is more distinct. The gums are less swollen and less blue. The wrists are smaller; ankles about as before. The milk was increased to 2 ounces. Mutton broth cooked with potato and carrots was given.

October 26: The appearance is still better. Moves hands and does not complain as much when touched. Anvles very little smaller than before. Food changed to: Cream, 8; milk, 4; otherwise as before.

October 28: Looks much better. Moves left hand freely, also feet. Wrists and ankles are smaller, but the left internal malleolus is still surrounded by considerable swelling. Milk changed to 5 ounces; other ingredients as before.

October 30: General appearance better. Moves all extremities actively. Gums less swollen; lateral upper incisors show through. Eyes, ankles and thorax about the same. While in the hospital the bowels were slightly constipated. The stools were of natural color and well digested. There was a positive test for occult blood (Dr. Cowie) on October 25, 26 and 27; negative afterward. The urine was not obtained, but the napkins showed no traces of blood. The temperature ranged between 101 C. on admission, and 98.6 C., usually between 99 C. and 100 C. Weight 15½ pounds.

Patient was discharged, with full directions for raw milk, milked with as much cleanliness as possible; aerated at once, filtered through cotton and kept on ice.

November 1: Returned for examination. Looks stronger. Moves more than ever before. Does not cry when handled. Discoloration on right eyelid clearing up. Eyes are further back than before. Upper gum is still spongy and red, but improving. Ankles and wrists about as before.

November 7: Patient sat up yesterday alone. Better in every way.

November 10: Examined in clinic. Moves extremities freely and sat up alone to day. Color good. Discoloration of right eyelid has disappeared. Left eye normal. The eyes are not prominent. The thorax is deeper. The gums are still slightly

swollen and red. Does not take orange juice as well as at first. Is taking 6 fluid ounces of milk in 20 ounces of the mixture. Weighs 16½ pounds. Food changed to cream 8 and milk 7 fluid ounces; other ingredients as before. Broths and gruels were also prescribed.

November 23: For two or three days has not taken food as well as before. Vomited once on the 19th, probably as the result of cathartic medicine. Looks stronger. Moves actively. Wrists are thick; ankles smaller than before. No discoloration. No tenderness. Gums natural; four upper incisors out; three below and fourth almost through. Costal cartilages still show groove, but body is more rounded than before. Advised five meals a day.

REMARKS.

Diagnosis.—Among the points of interest in the case diagnosis takes the first place. Like many similar cases, the true nature of this one was long overlooked. During this time the patient was in care of two physicians, in turn, of considerable experience and more than average ability. Neither had ever seen scurvy at any age, and they had only the usual knowledge of the less common diseases of childhood. But lack of actual observation of a similar case can not be a valid excuse in practical diagnosis. All progress in medicine would stop if it were. The physician first consulted discussed the case with a surgeon, who suggested neuritis without seeing the patient. The other suspected anterior poliomyelitis, but, not feeling certain, referred the patient to me. The chief cause of failure was the lack of a thorough examination, the cause of most faulty diagnoses. This was assisted by a failure to compare the findings with descriptions in text-books on diagnosis and practice.

A literary knowledge of the subject does not alone prevent error. Heubner tells us that in half the undiagnosed cases of infantile scurvy he saw in consultation the physicians in charge had a literary knowledge of the disease. Until I stripped the baby and examined its extremities, its mother and a very experienced and critical grandmother were not aware of the striking alteration in the shape of the thorax and the swellings and discolorations of the extremities. Had an examination been made, the first diagnosis of neuritis must have been given up on account of the absence of objective evidences of that disease and the presence of other features that could not be explained by neuritis alone. Then it would have been necessary to consider the possibilities that have caused error in other cases. Osteomyelitis, so often diagnosed, even to the point of causing operation, could hardly have been suspected in this case. In some, where the swelling has been greater and less symmetrical, only a complete examination and thoughtful differential diagnosis could prevent error. Against rheumatism, the relative constancy of the local lesions, the fact that they were not in the joints, the absence of superficial redness and of distinct fever would have been useful. On the other hand, the sweating of the head, if not considered in all its bearings, and the slight elevation of temperature, might easily confuse the diagnosis in this respect. Against sarcoma, the multiplicity and symmetry of the lesions, and the failure rapidly to increase should suffice. Against syphilis with pseudo-paralysis the condition of the parents, the age of the patient, the condition of the skin and mucous membranes, the absence of joint involvement and the great degree of tenderness, would be decisive. Anterior poliomyelitis was an insufficient diagnosis in view of the physical conditions. There was also no history of the onset of that disease, and the description of the course of the pseudo-paralysis was clear and agreed more with that of scurvy

than of infantile paralysis. Rickets would have been a better diagnosis, would have been partially correct, and, if made in time, should have led to a change in diet that would, in all probability, have prevented the full development of infantile scurvy. The case illustrates the importance in all cases of artificially fed infants of looking for rickets and the scurvy so often associated with it.

Critical examination of the mouth should have made it clear that the disease in the gums was not due to the incision, as was supposed, for it was also present in the lower gum that had not been incised. Further study of such anomalies must have led to a correct diagnosis of scurvy.

The proptosis and subcutaneous hemorrhage in the eyelids came on late. Diagnosis made in time should have prevented them. Although the orbital changes are relatively rare, the fact that E. Schlesinger has recently reported a case in which orbital hematoma was the first symptom in a case of infantile scurvy shows the importance of a general knowledge of the process. The article of Schlesinger¹ and that of Irving Snow² give a complete résumé of our knowledge of this interesting symptom. In regard to its incidence, the collective investigation of the American Pediatric Society gave only 22 cases out of 379, positively absent in 110. Heubner saw 4 cases out of 65. Barlow, who first described it, has also seen a case in which orbital hematoma was the only symptom. Snow shows the anatomic feature of the condition, a subperiosteal hemorrhage like the process on other bones, and Cohn's report of a case in which the hemorrhage came on suddenly, during a severe crying spell, suggests a traumatic element that is often present in the hemorrhages on the long bones. The successive affection of the two orbits, as in my case, is very frequent.

Etiology and Results of Treatment.—The study of the causal factors in the case reveals nothing new. There is the history, as in most cases, of a monotonous food, composed of a milk mixture that would not seem well adapted to the patient, and yet it seemed to agree fairly well for a longer time than one would have anticipated. The long-continued use of Mellin's food is of interest, but does not give any positive ground for conclusions. It is interesting to observe that severe gastrointestinal disturbance did not occur. The idea that a severe diarrhea or enteritis had been present was entertained by one of the physicians, but was not borne out by the clear and positive descriptions of the relatives nor by the examination of the stools. The bloody stools were certainly the result of the scurvy, without further implication of the intestines.

As in so many cases, we can not say whether the cause here was some qualitative or quantitative alteration of the food elements or some toxic substance, or all combined, in a patient long inappropriately fed.

Some other details of the feeding are interesting. The patient lived on a dairy farm, the herd being made up of Jerseys with a few Holsteins. As I learned later, the milk had undergone official tests and was good in every respect. When I began the treatment I was afraid to use raw milk, fearing the supply on the one hand, the gastrointestinal condition of the patient on the other. I therefore gave orders to Pasteurize the milk at 160 F., but by an error the method then in use in the ward was followed, and the milk was really heated longer than

2. "Eye Symptoms of Infantile Scurvy," *Archives of Pediatrics*, August, 1905, p. 576.

before and at a higher temperature. The only differences, then, were in the different source of the milk, an element that can not be analyzed, the withdrawal of the Mellin's food and the use of orange juice. Before anything else was given a distinct improvement was obvious, and recovery occurred while on sterilized milk, orange juice, and a small amount of potato and carrot broth. So rapid an improvement, of course, is not at all uncommon, and the change as soon as the orange juice is given, along with the curious avidity with which my patient took it, like so many others, seems to prove that it contains something much needed by the scorbutic body.

Skiagraphy.—My efforts to get an x-ray picture of the affected bones were not successful. It was impossible to make an exposure the first day, when the legs were spontaneously kept still. By the next day there was some motion when the noise and light of the apparatus were perceived, so that it was not possible to make a slow exposure with a soft tube that would show fine differentiation of the soft parts. The pictures, of which my colleague, Mr. V. H. Willey, made a number, show the swellings, as well as the appearances of the bones, but nothing more.

X-ray pictures of infantile scurvy have been published by Ausset, Rotch³ and Lemdorff.⁴ Those of Ausset and Rotch are not very good. Lemdorff's is given in a rather diagrammatic reproduction. The author says there were shadows along the femur and the tibia and fibula, and a clearing up of the bone shadow in all the bones. He explains the findings by assuming that the periosteum had had time to exert its osteogenic function, a belief that is borne out by postmortem examinations. Lemdorff, however, very properly warns against too much dependence on the skiagraphic diagnosis of infantile scurvy, though it may be of assistance in clearing up some of the anatomic changes.

AN ANTIGONOCOCCUS SERUM EFFECTIVE IN THE TREATMENT OF GONORRHEAL RHEUMATISM.*

JOHN C. TORREY, Ph.D.

Fellow in the Department of Experimental Pathology, Cornell University Medical College.

NEW YORK CITY.

The following communication is intended merely as a preliminary announcement of the preparation of an antigonococcus serum of therapeutic value. It will be followed shortly by an article in which the character and properties of this serum are dealt with in greater detail.

There are several reasons why an antigonococcus serum has not been used heretofore in the treatment of gonorrheal rheumatism. They may be tabulated as follows: First, there is not the slightest indication of an immunity in man to gonorrheal infection acquired by a previous attack; nor in chronic gonorrhea is the individual any the less susceptible to an acute superinfection. Second, there is no well-established case of an infection in animals with gonococcus. Wertheim, by injecting agar and gonococci together into the peritoneal cavity of rabbits, was able to produce a local peritonitis, but not a real infection. Heller's statement that he has produced an ophthalmic gonorrhea in young dogs by

injecting gonococci into the anterior chamber of the eye has not been confirmed. Third, it is generally supposed that gonococci can not be induced to grow luxuriantly under artificial conditions. Finally, most authorities agree with Wassermann and Nikolaysen in concluding that animals can not be immunized to the toxin of the gonococcus, as it is embraced within the cells and only diffuses into the surrounding tissues on its death and disintegration. In other words, according to their view, it is an endotoxin, a bacterial protein.

Although there was apparently slight chance of success, at the suggestion of Dr. Rogers I prepared a serum for a patient with gonorrheal rheumatism of some 15 years' standing, who had been treated in every other way without result. We were agreeably surprised to find the serum effective, not only in that case, but also in a high percentage of others in which it has been tried. These cases are fully described in the preceding clinical report by Dr. Rogers.

The culture which was originally employed in producing the serum was isolated from an acute case of gonorrhea in a male, who had not been treated. Gonococci were very numerous in the exudate, principally within the leucocytes. Smears were made from the discharge on petri dishes of aseptic agar. After an incubation of 24 hours, an almost pure culture of very small, transparent colonies appeared. These colonies were composed of small diplococci in every respect identical in morphology, staining reactions and cultural features with the characteristics of gonococci. The micro-organisms were negative to Gram's stain, would not grow on ordinary peptone agar or broth (repeated tests have been made extending over several months), and died out even on aseptic media in a short time. On aseptic agar (equal parts of aseptic fluid and 2 per cent. glycerin agar) the colonies are small and tend to remain separate. At first transparent and with regular edge, after four or five days the center of the colony becomes granular and the edge spreads out thinly and irregularly. All the diplococci have died in from six to eight days. In aseptic broth the length of life is much greater, from thirty to forty days.

For purposes of inoculation, a very satisfactory medium has been found to be a mixture of rich aseptic fluid and slightly acid beef infusion peptone broth in equal parts. Tubes of about 12 c.c. of the mixture are heated to 60 C. for several hours and tested for sterility. To obtain the best results, the temperature of the incubator should be between 36 and 37 C. Gonococci are killed at a relatively low temperature (at from 40 to 41 C., according to Scholtz). After from 18 to 24 hours' incubation, a slight granular growth appears near the surface and along the side of the tube. This slowly increases in amount until, after six days, the medium is well clouded on shaking. Other strains of gonococci which have been used form, after four days, a rather thick and flaky pellicle. In all the strains the growth after a time sinks to the bottom of the culture tube.

Various modifications of the proportion of the ingredients in aseptic broth have been tried, such as the presence and absence of peptone, increase in the amount of albuminous matter and aseptic fluid, but no combination has proved, on the whole, more satisfactory than the one which has been described.

It is interesting to note that the strain of gonococcus which was first used, after being cultivated for over a year on aseptic media, grows fully as well and produces as effective a serum as when first isolated. This is in harmony with the well-known fact that gonococci, iso-

* Read before the New York Academy of Medicine, 1905.

lated from chronic cases, have suffered no loss in virulence or growth energy. Two other strains of this organism, which were kindly given to me by Dr. Elser, have been found to give rise to fully as efficient a serum as the original culture. These were isolated from cases of vaginitis.

Large rabbits have been used exclusively in producing the serum. They were inoculated in early stages of the experiments at intervals of three or four days with about 10 c.c. of the entire culture. It has been found, however, that the results are rather more satisfactory if an interval of five or six days elapses between the inoculations. The animals thrive much better if so treated and bleed more freely. Experiments have been carried on with the idea of determining the most suitable age for the cultures used in inoculations. It has been found that both very young cultures, from two to five days old, and old cultures, from twenty to thirty days, produce a serum that is fairly satisfactory. The best results, however, are obtained with cultures from six to fifteen days old. During this period the cell growth reaches its height and the culture contains the greatest amount of toxin. Experiments on guinea-pigs also point to this conclusion. The inoculations are always made intraperitoneally.

According to Wassermann, no immunity can be produced in mice or rabbits to gonotoxin, although these animals may exhibit a slight resistance and adaptation. It has been my experience that rabbits and guinea-pigs show individual differences in their powers of resistance to repeated doses of gonotoxin, and that possibly in no case is there a true prolonged active immunity. The first inoculation always causes in rabbits a great loss of weight, sometimes amounting to one-fourth of the total weight. If the amount of toxin in the first inoculation is not too great and the animal is allowed to recover completely from its effect, the second and four or five subsequent inoculations give rise to only a slight loss of weight and discomfort. After a variable time, however, the majority of the animals reach a condition of hypersensitivity to the toxin and succumb finally to a dose that would never prove fatal to a normal animal. This seems to indicate, as Wassermann and others have pointed out, that the toxin present in the culture is, for the most part, if not entirely, derived from the dead bodies of the cells. When rabbits reach this hypersensitive stage, they refuse to eat and finally die in a greatly emaciated condition.

The rabbits are bled for the first time after they have received six inoculations, or about 60 c.c. of the culture, extending over a period of about a month. The most economical method is to bleed from the ear (which has been carefully shaved, washed with a germicide and finally with sterile normal salt solution) until the animals show signs of becoming hypersensitive, and then from the carotid. Large animals should yield a total of from 70 to 90 c.c. of serum. It is interesting and important to note that serum derived from one of the later bleedings is more potent than that obtained at first, when the animal has received only a few inoculations. Some rabbits, too, produce a better serum than others. It has also been found that the serum loses little, if any, of its power after remaining in the ice box for from one to two months. For distribution, small sealed glass tubes holding about 2 c.c. of serum are used. No preservative is added to the serum. With ordinary precautions it may easily be obtained sterile.

It is obviously a matter of interest to determine to

what factors in the serum its curative properties are due. In inoculating rabbits, whole cultures, both the cells and the filtrate, were used with the hope that a serum might be produced possessing both antitoxic and bactericidal factors. Although the majority of those who have investigated the subject believe, with Wassermann, that the toxin of the gonococcus is not of such a character as to bring about the production of an antitoxin when injected into animals, still one observer, de Christmas, claims to have obtained from old cultures an extracellular toxin, which, when injected into the brain of a guinea-pig, kills in very small doses. He believes that this toxin is produced by a vital process of the cell and is analogous with the extracellular toxins of diphtheria and tetanus. This toxin, however, is produced in considerable amount only when a special culture medium is used, consisting of one part strongly albuminous peptone-free broth and three parts aseptic fluid. By inoculating rabbits and goats with the filtrate of old cultures he apparently obtained a serum with sufficient antitoxic power to neutralize twenty times its volume of toxin. Although I have not found that there is any very decided increase in the amount of toxin produced by the use of the formula of de Christmas, my experiments, so far as they have been conducted, tend to confirm his assertion that it is possible to obtain an antitoxin for the toxin of gonococcus. This seems probable, on the one hand, from the protective power of the serum for guinea-pigs. Two pigs were given 1 c.c. of serum and one pig 2 c.c. Eighteen hours later these three pigs, and also an additional control pig, which had received no serum, were inoculated intraperitoneally with 3 c.c. of toxin. In one hour the temperature of the control pig had dropped over 10 degrees, and in three hours the animal was dead. The three pigs which had been treated with serum suffered only a slight drop in temperature and showed practically no signs of an intoxication. The details of these experiments will be given in a subsequent paper.

The clinical evidence also points to the same conclusion. In some cases there is a decrease of pain in the joints within twenty-four hours after the first administration of the serum. The most reasonable explanation of this result seems to be that some of the gonotoxin, which causes the inflammation and the attendant pain, has been neutralized.

Without doubt, however, the most important permanent relief which the serum affords in most cases is due to a bactericidal activity. In chronic gonorrhea there are comparatively few gonococci, often deep in the tissues, but, as an active immunity never arises in man to gonococcus, the system frequently finds difficulty in disposing of them. It seems possible that the serum supplies enough immune bodies to accomplish this, although too few to bring about the destruction of the great number of gonococci which are present in the urethra in acute gonorrhea. This theory has not been substantiated as yet by complete experimental evidence. The serum, however, has been found to contain both agglutinins and precipitins for the gonococcus.

Honorable Dealings.—It is a question whether the testimony given in suits for damages, against railroads and other corporations, is not at times biased by the knowledge that the physician will get no fee for his attendance, if the patient fails to "recover" for his injury. I was once asked to give a note saying that I was too busy to come to court to testify, because it was known that my opinion would be unfavorable to the cause of the plaintiff. Does anyone doubt that acceding to the request would have rendered the payment of my bill more certain?—J. B. Roberts.

THE TREATMENT OF GONORRHEAL RHEUMATISM BY AN ANTIGONOCOCCUS SERUM.*

JOHN ROGERS, M.D.

Surgeon to Gouverneur Hospital, Assistant Surgeon to St. Francis Hospital.

NEW YORK CITY.

Cases of gonorrheal arthritis can be grouped roughly in three classes—those which are mild and recover quickly; those which are severe and run a prolonged course; and those few which continue indefinitely. From what is known of other infectious diseases, it is very evident that the prolonged cases of this infection must lack the antibodies which naturally exist or are produced in the vast majority of individuals. If these antibodies could be provided artificially recovery ought at least to be accelerated, and with the specific object of thus benefiting the patient whose history is given in Case 8, I proposed the scheme to Dr. John Torrey, the bacteriologist in the experimental laboratory of Cornell University Medical College. He follows this clinical report with one describing the details in the manufacture of an antigonococcus serum.

The gonococcus is somewhat peculiar in its pathogenic limitation to man. Inoculations of pure cultures of the micro-organism into the various organs and tissues of other animals produce little or no reaction, and even in man repeated subcutaneous injections of considerable amounts of such a culture have caused only slight or transient local inflammation. Furthermore, there is still doubt as to how the human urethra recovers from the infection. It is not because the gonococcus has its vitality lowered by residence in this organ, because in chronic cases the organism retains its virulence unimpaired and can excite as acute an inflammation as any new culture. Nor does a true general immunity arise, as infection, reinfection and superinfection in the same individual are common. Recovery, therefore, seems only explainable on the ground that the mucous membrane gradually becomes an unsuitable culture medium. The susceptibility of a mucous membrane also varies with its location and the age of the patient; the conjunctiva, for example, is very easily infected during infancy and much less so during adult life. The same is true of the vaginal mucosa, as epidemics in little girls are often observed, while women who have borne children are comparatively insusceptible. The reverse is true of the endometrium, which is much more easily infected after puberty than before. Contrary to the general opinion, the mucous membrane of the bladder and pelvis of the kidney is quite resistant, and the nasopharyngeal tract is almost never attacked. The penetration of the gonococci into the deeper layer of the epithelium, its proliferation and desquamation, the exudation of the serum and emigration of leucocytes, in which the gonococci are found from the early stages of the process, are familiar facts. It is not so well known, however, that there is probably no true phagocytosis in the sense that the leucocytes destroy the gonococci by ingestion. They may even help to disseminate the micro-organisms by carrying them into the general circulation, although this explanation of systemic invasion is not necessary, as they have been found in abundance, free in the submucous capillaries and lymphatics and inguinal lymph nodes. The injurious effect of the infection is probably produced not by a true toxin, but by a bacterial proteid which is liberated by the death of the micro-organism.

The local complications produced by direct extension of the disease into tracts which are in continuity with the original focus do not come within the scope of this article, except as they illustrate the possibilities of suppurative inflammation. For buboes and periurethral abscesses have been repeatedly found to yield only a pure culture of the gonococcus. Of course, mixed infections are common, but the probability, or even the possibility of a pure gonorrheal infection in any of the complications of this disease should have an important bearing on the treatment here offered.

The term gonorrheal rheumatism seems particularly appropriate, as by analogy it calls attention to a systemic infection which most commonly manifests itself by serious disease of one or more joints, and less often involves other organs. It invites comparison with the ordinary acute polyarticular rheumatism, in which the microbic cause of the almost exactly similar lesions is as yet not proved. After entering the general circulation the gonococcus shows a marked affinity for the serous membranes, and, in addition to the common disorders of joints and tendon sheaths which it produces, there are enough cases on record of endocarditis, pericarditis, pleurisy and meningitis, due only to the gonococcus, to make one attribute to this organism any such complication in a patient giving a more or less recent history of gonorrhea. Cases of iritis, myelitis, myositis, neuritis and skin eruptions, and also subcutaneous and bone inflammations and abscesses and true gonorrheal septicaemia, i. e., cases in which the gonococcus is demonstrable in the blood, are reported and are mentioned as more than occasional possibilities. They all emphasize the gravity of the systemic infection which has occurred in every case of gonorrheal arthritis. One or more of the large joints, seldom those of the fingers or toes, may be attacked at almost any period after the incidence of the gonorrhea, the usual time being between the first and eighth week. It is generally considered necessary for the infection to have extended to the deep urethra before a systemic invasion can occur, but this belief is untenable, as there is on record a case of gonorrheal arthritis in an infant which followed a gonorrheal ophthalmia. It is evidently a complication which can occur from such an infection in any locality and in any stage.

The first symptoms of joint involvement are, of course, pain and disability. Swelling follows within a few hours, at first from serous effusion into the synovial membrane, and later from a diffuse edema of all periarticular structures. This edema is much more prominent than the intra-articular effusion. There is usually not much temperature or local redness, and it is more common for the affection to be monoarticular than polyarticular. It is quite characteristic for the chart to show a fever of from 101 to 102 F. for the first two or three days of the joint infection, and this probably marks the period of systemic invasion. After this the temperature curve, unless suppuration occurs, stays close to the normal point. The disease runs a rather slow course for several months and tends to gradual recovery, but it is often more violent and accompanied by high fever and suppuration, which may destroy one or more joints and endanger life from exhaustion or from other metastases. Rarely there may follow a very chronic condition, as in two of the cases cited below, which terminates in a condition indistinguishable without the history, from an arthritis deformans, with destruction and ankylosis of nearly all the joints in the body. Experience seems to prove that practically every joint lesion which arises in the course of a gonorrhea, even when there are no signs

*Read before the N. Y. Academy of Medicine, 1905.

of the original disease except a few gonococci in the "shreds" obtained from the urethra, can be pretty safely attributed to this organism. Ordinary polyarticular rheumatism and other arthritic troubles can be considered only after the gonorrheal arthritis is excluded. Differentiation from tuberculosis is the most difficult, but the x-ray should show the usual osseous character of this process, which almost never occurs in gonorrhea, and if this fails no harm can come from a trial of the antigenococcus serum.

This question of diagnosis needs considerable emphasis, because I am convinced a great many cases, especially those in women, escape detection. In the early stages the resemblance to polyarticular rheumatism is very close, as at first one joint, then another, may be attacked, and the attack in one or more joints may be somewhat evanescent and subside rather quickly, but there is almost always a joint which will continue diseased, and this in the later stages will lead to confusion with tuberculosis. There is the same diffuse thickening around the joint, often with the apparent or real production of new bone. In addition, to complete the similarity, there is atrophy of the muscles above and below the joint and the general appearance and attitude characteristic of tuberculous disease. Or in the later stages, if several joints continue affected, it is very difficult to rule out an arthritis deformans. In all these cases the essential point in making the correct diagnosis is the history. If there has been a urethritis or a vaginitis a few days or weeks before the onset of joint symptoms a gonorrheal infection is almost certainly at the bottom of the trouble. The x-ray, as stated above, may be of great assistance, and to this can be added a trial of the antigenococcus serum, which, if the diagnosis is correct, will relieve the pain within a few days. Very little reliance, however, can be placed on finding the suspected organism in the fluid aspirated from such a joint.

The gonococcus lodges and grows in the synovial membrane alone and apparently only for a short time, as it can not be found in the exudate after the first week or ten days, and it has not been found in the periartritic edema. It may, of course, escape from the joint (or tendon sheath) as the result of suppuration, and has thus been found in the neighboring abscesses, but by its presence there is usually excited only a serous or serofibrinous exudation with thickening of the synovial membrane.

The onset is acute and is followed by a rather slow course, with more or less damage to the joint from fibrillation of the cartilages, intra-articular adhesions and contraction of the ligaments, but ultimate recovery under careful treatment is the rule. Less commonly the exudate is purulent and the process is accompanied by the destruction inevitable in a suppurative inflammation in a joint, and bony ankylosis is about the best result to be expected. Even in these cases the reports seem to prove that the majority are due entirely to the gonococcus and that a mixed infection is unusual. When an additional infection does occur it has generally been with the *Staphylococcus albus* and less often with the streptococcus, and this possibility must not be forgotten in judging the results obtained by an antigenococcus serum. Fortunately for the diagnostician, however, nearly all the joint and serous membrane affections arising in the course of a gonorrhea can be pretty safely ascribed to this organism.

The ordinary antirheumatic treatment is notoriously unsatisfactory. Freely opening and washing out the

joints with more or less strong antiseptics has given somewhat better results, but unless suppuration is present it only slightly accelerates recovery and imposes the additional risk of a mixed or pyogenic infection. If, however, there is any evidence of the existence of pus, free incision, irrigation and drainage with every antiseptic precaution is, of course, always indicated. In every suspicious case, however, from twenty to sixty minims of the antigenococcus serum should be administered every day, or every other day, beginning as early as possible after the arthritic complications appear and continuing until the pain and disability subside. I have usually given it in the loose tissue overlying the fascia in the back of the upper arm. There is generally a noticeable improvement at the end of twenty-four or thirty-six hours, and within a week or ten days there is an almost complete subsidence of the disorder if it is acute. After the suspension of the medication there seems to be a constant danger of recurrence or recrudescence of the arthritis, especially if the urethritis persists, and the inoculations may have to be repeated. The whole course of the disease, however, is vastly shortened and ameliorated, and, beyond an occasional erythema, which may be observed after the use of any serum, absolutely no ill effects have been produced.

As to the prognosis, the earlier the disease is recognized and the earlier the serum is administered the better, of course, is the result. After the inflammatory process has continued for weeks or months and new tissue and adhesions have formed, or if destructive lesions have developed, the restoration to a normal condition may be very slow or may never occur; but even in these cases the serum will produce a more or less rapid subsidence at least of the inflammatory symptoms and the pain. The stiffness and the faulty motility must be overcome, as in similar conditions, by electricity, massage, passive motion and hydrotherapy.

This method of treatment has the same limitations and disappointments as all serum therapy and is not advanced as an infallible remedy. It must be borne in mind that the effectiveness of the serum depends on the animal and the culture which is used, the length of time and the manner that this animal is inoculated and the number of "bleedings" to which it is subjected. The serum obtained from the first bleeding does not seem to be as good as that obtained in the second or third bleeding. Then, even with the same serum, some patients react far better than others. An old chronic case requires more doses than an acute one, and there is even a considerable variation in the acute cases. In all except one of my cases, and that a chronic one (Case 7), the patients have shown some reaction in the way of improvement, even if not of speedy cure.

It must be remembered, however, that the serum has little or no effect on the urethritis, and as long as any traces of this persist there is a theoretical and real danger of recrudescence of the arthritic complications. Case 3 shows this very well. The gonorrhea persisted and a few days after apparent cure of the "rheumatism" the latter reappeared, but almost immediately subsided under energetic local treatment of the urethritis and a repetition of the serum injections.

The recrudescence of the arthritis after its apparent cure by this serum therapy, the rarity of the affection compared to the almost universal susceptibility of the urethra, the proved systemic resistance of man to experimental inoculation and the clinical observation that the same individual is prone to repeated attacks of arthritis with every fresh gonorrhea all suggest some difference

in the local and systemic resistance to the infection. The unfortunates who suffer from gonorrheal rheumatism must have a constitutional or congenital deficiency of antibodies, and as soon as these are supplied artificially the disease subsides. Furthermore, the serum seems to have no very marked effect on an existing urethritis or vaginitis. There was apparently some improvement in the course of the inflammation in the mucosa in my cases, but not enough to warrant the abandonment of the present reasonably satisfactory methods of local treatment or even to suggest that the urethritis is sensibly affected.

Objection may be raised to the lack of scientific accuracy in this report, as before administering the serum the gonococcus was not always identified except in the female cases (in the pus obtained from the cervix). In men the clinical evidence of the disease was generally deemed sufficient. This must be taken as merely a preliminary statement to call attention to the value of the treatment in cases of systemic infection.

The histories of the cases here submitted are examples of the common acute, chronic and prolonged forms of this joint disease, and although they are by no means all that have been tested, I have not omitted the failures. In a "prolonged" case, or one which continues for years and goes from bad to worse, a failure should not be judged harshly when the possibility of error in diagnosis is considered. Many good observers doubt the existence of such a condition and its explanation involves some difficulties, but in following the histories of these patients the more or less steady continuation of the same mildly inflammatory process seems to me conclusive evidence of the nature of the original infection, even if its indefinite prolongation is due to some superimposed alteration in nutrition or metabolism. That one of these peculiar patients was evidently benefited was certainly gratifying and encouraging.

CASE 1.—A. McC., aged 35, had the first gonorrhea seven years ago. The second began about two weeks previously, or on April 8, 1905. On April 22 he first noticed pain in the left knee, which increased during the next two days so that he was unable to move the leg.

Examination.—I first saw him on April 24. He then had a profuse purulent urethral discharge with frequent micturition. The left knee was swollen, held in semiflexion and exquisitely tender to touch and motion. There was very little effusion into the joint, most of the swelling being periarticular, and very little cutaneous redness.

Treatment.—Antigonoecoccus serum XXX was given hypodermically in the subcutaneous tissue in the back of the left arm, and a urethral injection of a silver solution was prescribed.

Course of the Disease.—On April 26, or two days later, this patient was found moving about his room with no pain or limitation of motion in the leg and was thought to be cured, but on April 30 he called at my office, complaining of a recurrence of the pain in the leg. There was some tenderness and a little thickening above the patella and another hypodermic of thirty minims of the serum was administered. The urethritis showed some improvement at this time. On the following day the pain and stiffness in the knee had disappeared entirely and did not again recur. The urethritis, under the usual treatment, subsided at the end of about two weeks more.

CASE 2.—H. L., aged 31, was admitted to Gouverneur Hospital November 26, with a temperature of 101 F. and a history of gonorrhea which had first appeared three weeks ago. For the past four days the right knee had been painful and swollen.

Examination.—The joint was held in the semiflexed position; there were slight redness and signs of considerable serous effusion. The synovial membrane above the patella seemed thickened and in this locality was more tender than elsewhere, although the region all about the joint was painful and sensi-

tive to pressure. The gonococcus was found in the urethral discharge (which had nearly disappeared).

Treatment.—On November 26, 27 and 28 forty minims of antigonoecoccus serum was injected into the subcutaneous tissue at the back of the upper arm—considerable local reaction followed, but no suppuration.

Result.—On November 27, or the day following the first injection, the fluid in the joints had diminished very perceptibly, and on November 29 no evidence of effusion could be detected. The improvement was marked and rapid, and, on December 2 this patient went home without any sign of joint disorder.

CASE 3.—S. C., aged 22, showed the first symptoms of a gonorrheal urethritis on Nov. 10, 1905, and on November 13, or three days later, the left knee became swollen and painful and on the following day the left shoulder was involved. He was brought to Gouverneur Hospital on November 17 in the ambulance, as he was unable to move the left leg or to bear any weight on it.

Examination.—There was a profuse purulent urethral discharge; the left knee was held in a semiflexed position and was exquisitely sensitive to pressure, especially on the inner side in the line of the joint. There was evidence of some serous effusion, but no redness and no edema. The left shoulder was painful and tender to pressure and held in an immobile position, but there was no swelling or other external evidence of disease.

Treatment.—On November 17, 19, 21, 24, 26 and 27 the man received from thirty to forty minims at a dose of the antigonoecoccus serum hypodermically in the subcutaneous tissue, first in one arm and then in the other.

Course of Disease.—There was an almost immediate disappearance of the trouble in the shoulder, but that in the knee subsided more slowly and the maximum point of tenderness shifted from the suprapatellar region to the tendon sheaths around the inner tuberosity of the tibia. On November 28 this had all disappeared and the patient began to walk, and on the following day went home apparently cured. The urethritis, for purposes of observation, had received no treatment and had shown only the improvement which might have been expected from the rest in bed. On December 5, after considerable exertion, the pain and swelling in the knee recurred, and he returned to the hospital on December 8, barely able to walk. The left knee joint was partially flexed, tender and swollen, and was distended with (serous) fluid. An injection of a silver solution was prescribed to be used after each urination, and forty minims of the serum were administered this day and the next, with striking benefit. On December 12 he appeared at the hospital for examination without any effusion in the joint and with no pain or tenderness and with no urethritis. He was dismissed cured, with directions to continue the urethral injections twice daily for another week.

CASE 4.—J. P., aged 29, had a gonorrheal urethritis in March, 1905, and the purulent discharge continued till June, when the left wrist became swollen and painful and he entered St. Vincent's Hospital.

Clinical History.—The condition was not at first recognized and all the antirheumatic remedies were tried without effect. On August 19 there had been little or no improvement and the left wrist measured two and one-half inches more in circumference than the right. There was little or no redness and very little edema, the wrist was partially flexed and the fingers extended; the swelling appeared to consist of new tissue and extended from the knuckles to just above the wrist. There was a noticeable atrophy of the muscles of the forearm and motion was impossible and the tenderness great. The whole picture was so like tuberculous disease that even with the history and the few "shreds" and pus cells discoverable in the urine the diagnosis seemed very doubtful.

Treatment and Result.—Thirty minims of the antigonoecoccus serum were administered hypodermically on August 19, 25 and on September 1, 3, 5, 7 and 9, with very marked benefit, and on September 11 the patient was discharged practically cured. The swelling had decreased so that there was only a half inch difference in the circumference of the two wrists. On November 10 this patient was shown to the Interurban Clinical Society at its meeting in the Cornell University Medi-

cal College; the only abnormality was a slight limitation to full flexion and extension in this wrist.

CASE 5.—J. A., aged 34, entered the French Hospital Sept. 18, 1905, with a slight subsiding urethritis and a history of pain, swelling and disability in the right wrist existing for two days.

Clinical History.—There was a temperature of 102 F., with headache, malaise and some diarrhea, all of which disappeared shortly afterward, but the wrist remained practically unchanged. On October 23 examination revealed a diffuse painful swelling of this wrist, which was held semiflexed with the fingers extended. Of the signs of urethritis there only remained a few shreds in the urine in which I was told that gonococci had been previously found.

Treatment and Result.—Beginning with October 23 and continuing until November 8 thirty minims of the antigenococcus serum were injected on alternate days into the subcutaneous tissue, generally in the back of the upper arm. Before the first injection the patient had required morphin every night to relieve the pain, but after the first injection this was no longer needed. The swelling and disability subsided very much more slowly, and on November 10, when this patient was shown to the Interurban Clinical Society at Cornell University Medical College, the result was not brilliant. The tenderness, pain and most of the enlargement had gone, but some of the new tissue and the many adhesions resulting from the inflammation remained, and the hand was still incapable of use. I did not, however, consider it a failure, as the signs of active disease had been dissipated. The results of the disease could only be cured by time and mechanical treatment.

CASE 6.—A. B., female, aged 17, gave a suspicious history of a syphilitic infection some two years previously.

Clinical History.—On April 20, 1905, she was admitted to the medical wards of the St. Francis Hospital with a history of vaginitis, urethritis and endometritis existing for a couple of weeks. During the past three days the left wrist and left knee had become swollen and painful. She was confined to bed and received all the usual antirheumatic remedies, without the least improvement until the gonorrheal character of the disorder was finally demonstrated in the pus obtained from the cervix. On June 1 she was transferred to the surgical division. The left wrist and the knee had the general appearance of the old-fashioned "tumor albus." There was very little redness over either joint and each was in a semiflexed position and extremely tender. The slightest motion caused great pain. In the wrist there was an even swelling and firm thickening which extended from the knuckles nearly to the middle of the forearm. In the knee there was the same diffuse periarticular edema and also thickening of the suprapatella bursa. The joint contained some fluid. There was perceptible atrophy of the muscles in the forearm and the leg. Without the history and the finding of the gonococcus in the cervical pus each of the joints might have been pronounced to be the subject of tuberculous disease.

Treatment.—On June 2 the first injection of thirty minims of the antigenococcus serum was given into the subcutaneous tissue on the back of the left upper arm. The next day an erysipelas-like bluish developed in the neighborhood of the injection and extended from the shoulder nearly to the wrist. This began to subside within a couple of days, but caused me to postpone the next injection until June 6, when thirty minims were given in the other arm. On the following day the pain in the wrist was much less and the knee showed some improvement. The injections were repeated on June 8, 12 and 15.

Result.—The wrist had lost all pain after the third injection, but, as might have been expected, it was somewhat stiff and did not regain full mobility for about two weeks. The inflammatory symptoms disappeared from the knee on June 16, when the patient was able to get out of bed for the first time since admission on April 20. From this time on there was steady, though somewhat slow, improvement; walking was begun on June 20 and she went home the following week. The wrist had entirely recovered, but the knee still had some limitation of motion.

CASE 7.—C. W., aged 31, suffered from several attacks of gonorrheal urethritis between 1893 and 1899.

Clinical History. In the latter year the metacarpophalan-

geal joint of the left index finger became swollen and painful and has continued in a more or less disordered condition ever since. The urethritis persisted as a "morning drop" and shreds in the urine were noticed for several years. In 1901 the right knee began to show pain and swelling and the disease gradually extended from one joint to another until in October, 1905, he entered Gouverneur Hospital. He was just able to move about a few steps at a time with the aid of crutches. Every large joint was tender and showed thickening of all the periarticular soft parts, but no redness; most of them revealed marked limitation of motion and the mobility which remained was painful; the muscles of the arms and legs were atrophied and the feet edematous; there was a subluxation of the right knee.

Treatment and Result.—For six weeks this man received samples of the antigenococcus serum from nearly every rabbit in the laboratory and it was impossible to detect any improvement. His case is described as a frank failure in the treatment and as an example of what I am firmly convinced is a chronic gonorrheal arthritis of the worst type like Case 8. This form of the disease is often doubted, but though rare, the history is so plain in the coincidence and coexistence of the urethritis and the arthritis that I can make no other diagnosis. In neither of these two chronic cases, however, could the gonococcus be demonstrated since they have come under observation.

CASE 8.—H. W., aged 39, had a first attack of gonorrhea in December 1887.

Clinical History.—This attack had almost disappeared, when in the first week of January he spent a whole day skating. The next morning the left knee was found to be swollen and painful and a few days later the right knee became involved. The probable origin of the difficulty was not suspected, and the urethritis shortly afterward disappeared, although he noted shreds in the urine for years. He never entirely recovered from the original arthritis, and though from time to time it improved, sooner or later another joint became inflamed. Every conceivable cure was attempted in this country and Europe, but after a year or two symptoms of arthritis deformans or a chronic rheumatism with intercurrent acute exacerbations in one or another joint were so prominent that no one seemed to have even suspected a gonorrheal infection. In 1901 he suffered from a rather severe typhoid fever. Before that period he had been able to get about in the intervals of acute attacks, though with increasing difficulty, with a cane or on crutches. After the fever, however, the former "rheumatism" returned worse than ever and he became bedridden. Then an iritis developed, first in one eye and then the other, and in course of time resulted in nearly complete loss of sight. It is interesting to note that about this period he underwent a rather prolonged course of treatment with the x-rays applied over the inflamed joints. The result was no improvement of the arthritis and an extensive severe dermatitis. He first came under my observation in November, 1904, and his pitiful condition and history prompted the work which resulted in this serum. The patient was bed-ridden, blind, with ankylosis of all the spinal joints, hips flexed, knees bent at a right angle and dislocated backward and with elbows, wrists, fingers and ankles swollen and inflamed. The only joints not affected were the temporo-maxillary and those of the toes. He had to be fed by a nurse and suffered constant pain.

Treatment and Results.—The injections of serum, from twenty to thirty minims at a dose, were begun in January, 1905, and given about twice a week until February. The inflammatory symptoms and the pain began at once to subside, but after the medication was stopped the disease reappeared again in the wrists, and the hypodermics were resumed and continued twice a week during March. After about the 1st of April there were no further signs of active inflammation and he became able to feed himself and to smoke a pipe. Then massage was begun and at present (October, 1905,) he is able for the first time in several years to sit in a chair. The bony ankylosis of the spine, the partial ankylosis of the hips and the subluxation and deformity of the knee joints and the blindness, of course, remain, but the freedom from active inflammation and the pain is a remarkable gain. There was only one hypodermic abscess as the result of some twenty or thirty injections.

THE "PATENT MEDICINE" AND NOSTRUM EVILS.

J. M. ANDERS, M.D., LL.D.

Professor of Medicine and Clinical Medicine in the Medico-Chirurgical College.

PHILADELPHIA.

Encouraged by a small measure of success resulting from the efforts put forth in the recent past to stamp out the "patent medicine" and secret nostrum evils, it behooves the medical profession at large to forward the beneficent effects of an awakening that has come none too early, until victory for reputable therapeutics and pharmacy is no longer in doubt. Individual members of our profession and medical organizations can aid the progress of this praiseworthy work by a calm, temperate, dispassionate discussion of the question, more particularly by pointing out the reasons for the phenomenal success of these doubtful preparations and by urging measures of relief in the interests of the public and professional weal. It is the province of the trained and disinterested physician to give appropriate and efficient direction to the movement.

THE NATURE OF THE BUSINESS.

It is well known that adulterants are extensively introduced into foodstuffs and medicines. This vicious practice is not of recent birth, but has long been carried on by the orientals. Such adulterations and falsifications have been gradually brought under the control of state and municipal authorities, but an even greater American curse has been allowed to grow and develop, without official molestation by a patient and long-suffering people—the "patent medicine" and nostrum enterprises.

It is well to recollect at the outset that a patented medicine is not a secret medicine, since the inventor or manufacturer must disclose the composition and also the process of manufacture; this information is obtainable on application to the patent office of the government. It is, however, protected for a given time, 17 years, after which period it becomes public property. On the other hand, the trade-mark nostrum, under which head come innumerable secret or semi-secret proprietary preparations, is a perpetual monopoly, and to this class belong so-called "patent medicines," which, however, have not been patented. Since the nostrums would have narrow chances of success without the patronage of physicians, and since also so-called "patent medicines" are supported principally by the general public, it seems to me that a divisional study of the subject based on this significant distinction is necessary.

The lay press, more especially such representative publications as *Collier's Weekly*, *Ladies' Home Journal*, and others, have already broken soil in the field of "patent medicines," and their efforts promise the richest harvest; they are fully entitled to the warmest gratitude of the medical profession, as well as of all who are truly desirous of promoting the social good.

To attempt to point out to a medical audience the capabilities for harmful effects of the many known "patent medicines" which are used by a confiding public would be a work of supererogation. Physicians also know that exorbitant charges are made for these preparations—a fact not yet realized by the general public. Indeed, the extent of the prostitution of talent and services to the injury of their fellow-men, by the venal manufacturers of these preparations, strikes one with painful astonishment. Numerous individual instances could be

cited to corroborate this statement, but it is enough here to refer specifically to peruna, which has been exploited by its quack owner as a certain cure for catarrh—a term so defined as to embrace nearly all human ills. The composition of this much-advertised preparation, according to analyses carried out by *Collier's Weekly*, is as follows: One-half pint Cologne spirits, 190 proof, and 1½ pints of water, adding thereto a little cubes for flavor and a little burned sugar for color. But peruna has many conspicuous rivals, and it is an interesting fact that, taking the different "patent medicines" at random, it will be found that alcohol in some form is, as a rule, the principal constituent.

Mr. Edward Bok has done telling pioneer work in creating public sentiment against the patent-medicine curse, and has catalogued a long list of preparations by name, giving the percentages of alcohol which each contains.

A glance at this list will convince the most skeptical that the percentage of alcohol contained in the various "bitters" and "bracers" is, on the average, higher than in spirituous and malt liquors, or the products of the saloon. It is a matter of observation that in places (e. g., prohibition states) in which whisky can not be purchased the consumption of patent medicines reaches its maximum. It would appear, therefore, that they have been conceived, manufactured and used quite outside of the sphere of legitimate medicine.

The principal objection to these nostrums, however, appertains to the well-known methods which have been and are adopted to exploit them. With an assumed devotion to mankind, which is only equalled by the love of the Tudor monarchs for flowers and gardens, and an implied burning desire to relieve suffering humanity from its manifold ills, attractive representations are made to the public, through advertisements, which, however, can be readily shown to be largely fictitious.

Unfortunately, the people of the work-a-day world, who are afflicted with chronic ailments of various kinds and degrees, whatever their mental training, are unconsciously credulous in the matter of the extravagant claims made in the newspapers and magazines by the vendors of "patent medicines." Moreover, the modern type of quack is quite able to appeal with success to the most cultured classes of society, so well has he or his hired advertisement writer mastered the art of seduction.

Females complaining of backache, and young men and boys, who believe what they read in newspapers and magazines about the meaning of their meaningless symptoms, become ready victims of a vicious class of swindlers. It appears to me, however, that many doubtful or so-called borderland nostrums, which are advertised in both the medical and lay press as being of great value in incurable conditions and readily prescribed by practicing physicians, are not less objectionable than the "patent medicines." At all events, they are scarcely accessible to the spirit of science. Obviously the present propaganda against the evil under consideration must be extended beyond the "patent medicines" to many well-known "proprietary" articles.¹

Again, the testimonials of widely-known persons, many of whom have attained to eminence in their respective callings, have stimulated and encouraged the use of nostrums. Here is a shining example: Mrs. Leslie Carter says of peruna: "It cures all catarrhal affections like magic. No money could tempt me to be

without this remedy for even a day." The columns of our newspapers and other lay periodicals as advertising media have been the principal or essential element in bringing about the pecuniary success of "patent medicines." While we need not stop to inquire what has been the motive or moral principle governing the universal action of the lay press in respect to its advertising pages in the past, it has manifested an obvious ambition for a quick financial return, to say the least. There is cause for exultation, however, in the fact that a wave of righteous public indignation has appeared on the horizon and bids fair to sweep over and extirpate the free field so long pre-empted by the quacks of this country.

Mr. Samuel Hopkins Adams has made the profession and public alike his debtor by giving a "full explanation and exposure of patent-medicine methods and the harm done to the innocent public by this industry." He has pointed out a number of great practical truths which can scarcely be over-emphasized. In the first place, as is well known to physicians, the long-continued use of certain drugs (e. g., cocaine, opium, arterial stimulants) will most certainly enslave the devotees to their use, and thus are the ranks of the drug fiend constantly recruited. Mr. Adams clearly echoes medical opinion in pointing out that the alcohol-laden "bitters," "sarsaparillas," and "tonics," taken daily and in increasing doses, make not for health, but for disease. Such information as this writer has been giving directly to the public will prove effective in lessening the annual outlay of moneys by Americans for medicines having little or no value for the conditions in which they are employed.

Having considered "patent medicines," I shall attempt to point out the reasons for a parallel demand for proprietary remedies and nostrums. At the outset, the fact is to be emphasized that it would be unjust to condemn all proprietary preparations; they are not objectionable provided that their composition be revealed and they are judiciously and honestly exploited. On the other hand, proprietary remedies that are secret or semi-secret in character, and the immense majority of the "proprietarys" belong to this category, are clearly condemnable. Every intelligent and properly-minded physician must concede that it is wholly unscientific to prescribe remedies of whose composition he is ignorant, or a mixture for whose reliability he can not vouch, and no one can deny that the medical profession has been a powerful and unfailing adjunct of the manufacturers of this class of remedies; they have been allowing the manufacturers of secret proprietary articles to compound their preparations and even to point out the indications for their use. Again, as Dr. Frank Billings² says, "many so-called medical journals are subsidized by medical manufacturers, and one-half of the medical journals of the country would be out of existence if it were not for the nostrum advertisements."

One of the most unfortunate aspects of the situation is the widespread control exercised by the Proprietary Association of America over both the medical and lay press. Moreover, the advertisements of the "proprietarys," be it observed, exhibit in a striking degree the same structure and method as those of "patent medicines," and they, together with the visiting agents, are chiefly responsible for the extensive employment of nostrums by overcredulous practicing physicians. In this connection, the claims of certain writers that the flagrant iniquities of many pharmaceutical manufacturers are

the natural result of modern therapeutic nihilism must be largely admitted. As elsewhere stated, "Our colleges of medicine and pharmacy are scarcely alive to the moral responsibility involved in this gravely threatening evil. The teachings of these schools should be of such a character as to enable students to discriminate between genuine and spurious remedial agents."³

The principal neglect on the part of the medical schools affects the science and art of pharmacy, and on this question the editor of *American Medicine*, in a recent issue, pertinently remarks: "The revolt against these nauseating mixtures of the past generation of physicians was, in part at least, a cause for that remarkable stampede toward homeopathy which this country witnessed. All the work of discovering proper methods of administering drugs has thus been left to the pharmacist. The tendency toward therapeutic nihilism would certainly have become a great evil but for the pharmacist, to whom the medical profession certainly owes a great debt of gratitude."

Unquestionably, the time is ripe for the inauguration of a campaign of education among physicians and college faculties in the interests of legitimate, scientific therapeutics and pharmacy.

HOW TO COMBAT THE BUSINESS.

I shall next deal with various measures and methods for the cure of the nostrum evils. In the first place, a most timely organized effort has been instituted by the American Medical Association, with the object of exposing the evils of the preparations under discussion, of determining their precise composition, and showing the extent of the harmful effects which they produce. To THE JOURNAL of the American Medical Association belongs the credit of suggesting the formation of a board of control, with the double object of reviewing all medical preparations offered for insertion in the advertising pages of that journal, and of giving a description of the unofficial preparations, which conform to the required standard, the whole to be issued in a work supplementary to the United States Pharmacopoeia, to be entitled, "New and Unofficial Remedies."

Furthermore, the board of trustees of the American Medical Association has authorized the creation of a Council on Pharmacy and Chemistry, which proposes to examine into the composition of the numerous and varied preparations that are constantly offered to the medical profession independently of the United States Pharmacopoeia. Up to the present time the investigations have been confined principally to proprietary nostrums, on which the editor of THE JOURNAL of the American Medical Association has wisely commented as follows: "Before we can proclaim war on patent medicines with energy and a clear conscience, it will be necessary for us as physicians to rid ourselves of the proprietary nostrum evil by ceasing to prescribe preparations that are nothing more nor less than patent medicines. Before medical journals can criticize newspapers for carrying patent medicine advertisements, they must themselves refuse advertisements of similar preparations, even though these be dignified with the name of proprietary medicines."

It should be stated here that the secretary of agriculture has organized in the Bureau of Chemistry of that department a drug laboratory for the investigation of the purity, adulteration, false labeling and false brand-

² "The Nostrum Evil," THE JOURNAL A. M. A., Dec. 2, 1905.

³ Anders: "The Curriculum of the Scientific Professional College," THE Medical Bulletin, October, 1905.

ing of drugs. This laboratory, which was established about two and a half years ago, has accomplished much valuable work, and the bulletins issued from it can be secured by addressing a request to that effect to the secretary of agriculture. More recently, the agricultural department, at the request of the postmaster-general, has investigated certain secret remedies and nostrums, as well as the advertisements offered for transmission through the mails. As a consequence, the literature pertaining to the nostrums investigated has been excluded from the mails, and to this extent the public has been protected against fraudulent allegations.

In commenting on the important work undertaken by the postoffice and agricultural departments at Washington, Dr. W. H. Wiley⁴ remarks: "In the interests of the medical profession, of the pharmaceutical profession and of the public, it is hoped that federal control of drugs in general may become universal and more efficient. In this way the interests of the two great professions mentioned, and of the public, can be best conserved." As measures of relief for the evils under consideration, the combined results of the labors of the lay press, the medical press, the Council on Pharmacy and Chemistry of the American Medical Association, and the two departments of the United States government mentioned above, can not be overestimated, and through these channels both the general public and the medical profession are receiving reliable, impartial information on the subject.

In attempting to deal with this great problem, however, its financial aspects must be reckoned with, since men engaged in this nefarious business pay annually enormous sums of money to newspapers, magazines and medical periodicals for cunningly executed advertisements of a deceptive character. It has been estimated that the yearly amount expended for "patent medicines" and other nostrums exceeds \$100,000,000—"more than one thousand dollars to each daily, weekly and monthly periodical in the country." The query, Can the mutually profitable financial relations existing between the press and the patent-medicine makers be severed? is pertinent. A few high-class secular periodicals, e. g. *The Outlook*, *The Evening Post*, *Life*, *Collier's Weekly*, and *The Ladies' Home Journal*, refuse to accept such advertisements, thus showing an ardent desire to break up this illicit combination. We may be assured that a thorough appreciation of the beneficial results to the public resulting from this attitude of the lay press will prove to be an incentive for emulation, and that eventually, as the result of the upheaval in progress, all reputable publications—both medical and lay—will be lifted to the same high, ethical level.

On the other hand, to my mind, the great American evil could be more effectually remedied by a comprehensive legal enactment compelling all makers of proprietary articles to place the formula on the bottle. Legislation could be of further service by insisting that preparations containing poisons must be labelled accordingly, while those containing alcohol must give its precise percentage. Under these circumstances, laudatory advertisements would no longer suffice, for the simplicity of their composition and the absurdity of the extravagant and unfounded claims made for them as therapeutic agents would be known to the general public. Such legislative action has been taken both in the state of North Dakota and by the New Zealand parliament.

According to Dr. Syme,⁵ there followed in the last-named country a storm of protest by the manufacturers of "patent medicines" and their agents, which led to a modification of the regulations to the extent that the formula was to be lodged with the Health Department. But the manufacturers still objected and they decided not to send their medicines to New Zealand, realizing, as this writer observes, that "they would have no demand at the extravagant prices at which they had hitherto been sold."

The patent medicine manufacturer is quite aware of the fact that so soon as the public shall have been made acquainted with the composition of his fraudulent preparations popular support will be promptly withdrawn. It is, however, impossible to foresee the time when state legislative action shall have progressed to the point of accomplishing the coveted practical good, owing to the existence of organized opposing forces, such as the Proprietary Association of America, and other influences. Meanwhile it seems to me that the work of educating the people at large devolves naturally on physicians and pharmacists (although up to the present undertaken principally by the lay press), even at the risk of being denounced as actuated by self-interest.

It is of the utmost importance to make the public understand, as the result of the present crusade, that the "demonstrations of popular sentiment" in favor of these nostrums are absolutely fictitious, that they are inspired by the unwarranted claims of the manufacturers, and that advertising contracts exercise a controlling influence over the lay press, especially in the rural districts. The popularizing of such information would at least compel manufacturers to guard and moderate the unfounded claims of their patented and proprietary articles. May we not indulge ourselves in the hope that a properly directed, energetic and unceasing agitation of the subject, in the absence of efficient protective legislation, may compel the adoption of the habit of placing the formulas on the bottle?

As touching the secret proprietary articles, which are advertised principally in the medical journals, it is assuredly the province of our profession to create an appropriate professional sentiment, and to disseminate thoughts and data, that will bring medical men in touch with those influences that make for a higher moral and ethical standard. No other factor would be so influential as an uplifting force in this prodigious task as the united medical press. THE JOURNAL of the American Medical Association has had the courage and independence to give to the medical profession of this country the true situation regarding the nostrum evil in a truly scientific spirit, and is rapidly eliminating the advertisements of articles of an objectionable character from its advertising columns. As stated above, a certain number of high-class lay journals are refusing to accept the advertisements of unethical "patent medicines," and the question naturally arises, Can the best medical journals afford to occupy any longer a lower ground with reference to the secret proprietary articles? A movement of this sort should include the education and enlightenment of the general public—a course that would, in turn, give greater scope and meaning to all professional sentiments and lines of action. So long as the community is opposed, or even indifferent, to the endeavors of the profession to correct the abuses under discussion, just so long will the deep-rooted inclination of the populace to

4. THE JOURNAL A. M. A., Dec. 3, 1904.

5. International Medical Journal of Australasia, quoted by THE JOURNAL A. M. A., Nov. 4, 1905, p. 1422.

disregard or even combat new ideas and methods defeat our best efforts.

Finally, the profession must adopt a general plan of action if it would hope to execute a winning fight against the great wrong, and I would respectfully submit a series of lines of attack to be included in such a plan:

1. Agitation through co-operative effort on the part of high-class journals, medical writers and medical organizations with a view to enlightening the profession and elevating the standard of the profession.

2. The enlightenment of the public by the agencies noted under 1 with the aid of the influential lay press, which has already rendered excellent pioneer service.

3. Medical schools and medical journals should aim to educate physicians regarding official preparations and proprietary articles whose composition is known and of proved usefulness.

4. The proper training of medical students in the science and art of pharmacy, including prescription writing.

5. Co-operative effort on the part of physicians and scientific pharmacists is to be encouraged, e. g., such as the admirable work that is being carried out by the Council on Pharmacy and Chemistry of the American Medical Association.

6. Continued exposure of "patent medicine" and nostrum methods and the disclosure of the composition of these preparations by the lay and medical press (to the public) is urgently needed.

7. The creation of a professional sentiment to the effect that trade-marked nostrums are unworthy of being prescribed.

8. Attempts to emancipate a shackled medical and lay press must be persistently maintained.

9. The enactment of appropriate legislation—a line of action in which it will be hard to demonstrate practical results in the immediate future, owing to powerful organized opposition.

10. The furtherance of the aims of the upheaval in progress by completing the organization of the medical profession of America in accordance with the plan proposed by the American Medical Association in 1900.

SODIUM AURATE: A NON-IRRITATING LOCAL ANTISEPTIC OF REMARKABLE POWER.*

F. H. VERHOEFF, A.M., M.D.

Pathologist and Assistant Ophthalmic Surgeon, Massachusetts Charitable Eye and Ear Infirmary.

BOSTON.

The need of an antiseptic combining effective germicidal power with lack of toxicity to the tissues is well known. So many chemical antiseptics have been tried without success that the belief has become prevalent that no chemical substance could possibly fill these requirements. In fact, attention has been directed of late almost exclusively to the development of serum therapy, which, however, has yielded but few practical results. The problem has presented itself to me particularly in connection with gonorrhoeal ophthalmia. Here it would seem easy to overcome the infection by means of local applications, yet thus far no satisfactory antiseptic has been available for this purpose. After many failures in attempts to solve this problem, I believe I have found an antiseptic which will prove of great value not only in the treatment of infections of the eye, but also in the

treatment of many other conditions in which the use of a local antiseptic is indicated. In this communication the method of preparing the antiseptic will be given and the experiments which demonstrate its bactericidal properties will be described. While in the cases in which it has been tried it has given most gratifying results, as yet these are necessarily few in number, and a full report of its action in a series of clinical cases must be deferred.

PREPARATION.

The antiseptic is prepared as follows:

One gram (15 grs.) of gold chlorid¹ is dissolved in 50 c.c. distilled water. To this is cautiously added sufficient of a 5 per cent. aqueous solution of sodium hydrate to produce a faintly alkaline reaction with ordinary litmus paper. As the process of neutralization approaches the stage desired the fluid becomes lighter in color and also slightly turbid. One hundred c.c. of a 1 per cent. solution of boric acid is then quickly added and the whole thoroughly shaken. This should cause the turbidity to disappear and the fluid to turn somewhat darker in color. If the turbidity persists, it indicates that too much sodium hydrate has been added. The total volume should now be made up to 200 c.c. with normal saline solution, filtered and kept in a glass stoppered bottle. The final solution should give a faintly acid reaction. While, as will be shown, the gold does not exist in the fluid as a chlorid, for practical convenience the strength of the fluid is best expressed in the percentage of gold chlorid used in its preparation. The above solution will, therefore, be designated as a $\frac{1}{2}$ per cent. solution. A 2 per cent. solution may be prepared from which the lower percentages may be obtained by dilution, but it is much more difficult to arrive at the proper degree of acidity in the higher strength. By evaporating the fluid to dryness the antiseptic may be obtained in powder form from which an ointment can be prepared.

The bactericidal properties of this fluid are dependent on the presence of gold. It is the partial or complete neutralization of the fluid, however, that renders possible its use as a practical antiseptic. The boric acid is not an essential constituent and is added only to avoid a practical difficulty. This arises from the fact that in order to prevent precipitation the fluid must be sufficiently acid, while if too acid it is highly irritating to the eye. The boric acid neutralizes any slight excess of sodium hydrate and ensures an acid fluid free from irritating qualities. If, through mistake, too much sodium hydrate has been added and precipitation has taken place (which may not occur until after twenty-four hours) the precipitate can be dissolved by adding an excess of hydrochloric acid and the acidity again reduced to the proper degree by sodium hydrate. When properly prepared the solution remains stable indefinitely.

The chemical reactions which take place in the preparation of this fluid are assumed to be as follows:

Further reaction is prevented by the boric acid, which reacts with the excess of sodium hydrate, thus—

The final constituents of the fluid, then, are in all probability sodium aurate, sodium chlorid, sodium borate and boric acid. Of these it is obvious that the sodium aurate alone gives the bactericidal properties to the fluid. It is hardly necessary to state that the antiseptic could be prepared by the use of other compounds of gold and of the other alkalis, but the method here given seems to be the most convenient.

* Read before the New England Ophthalmological Society, and before the Boston Society of the Medical Sciences.

1. Chlorid of gold may be obtained from wholesale druggists or from dealers in photographic supplies. Although sold under this name it is really hydrochlorauric acid, HAuCl_4 . The pharmacopoeial preparation, chlorid of gold and sodium may be substituted if used in double quantity. It is, however, more expensive.

When prepared as above this fluid, in strength of 0.5 per cent. gold chlorid, may be repeatedly dropped into the conjunctival sac without producing any feeling of irritation or giving rise to hyperemia. After a time a peculiar sticky or dry sensation may be experienced, and one or two patients have spoken of an occasional blurring of vision after its use. This is not due to mucus or other secretion, but probably to small collections of desquamated epithelium brushed across the cornea by the lids. The 1 per cent. solution produces some slight irritation, but judging by the bacteriologic tests, for most purposes this is unnecessarily strong. If the 1 per cent., or even the 2 per cent., solution is made faintly alkaline in reaction it loses its irritating qualities, but unfortunately will undergo precipitation within a few days. Where it is necessary, however, to make use of the stronger solution it can be prepared fresh every day from two stock solutions, one containing the gold and the other the alkali in suitable proportions. The alkaline solution has fully as strong bactericidal properties as the acid solution. The only disagreeable feature of the fluid, whether acid or alkaline, is that it stains about everything on which it is allowed to dry, including the skin. It does not irritate the latter, however, and the stain wears off in a few days. If not too old the stain may be removed from linen by means of Lugol's solution. Fortunately the fluid does not stain the conjunctiva or cornea. While, as already stated, the fluid is stable when properly prepared, it undergoes a certain amount of precipitation when foreign particles are added to it by the repeated insertion of eye-droppers. It is, therefore, probably best to renew frequently the fluid used by the patients.

BACTERIOLOGIC TESTS.

The bactericidal power of the antiseptic was tested by placing one-half to one c.c. in a small sterile glass vessel, stirring into it organisms from a 24-hour-old culture, and taking cultures from the mixture at definite intervals. An amount of bacterial growth equal to several colonies was always stirred in so that the fluid was rendered distinctly turbid. In making the cultures one large loop full of the fluid was transferred to the water of condensation in a blood serum culture tube, the latter shaken and the water flowed over the solid medium. The culture tubes were especially prepared with an extra amount of water for this purpose. By this method the number of bacteria killed in a given time was quite accurately indicated by the number of colonies which grew out on the solid media. Thus, in case all the cultures taken were positive, the length of exposure necessary to kill all the organisms could be closely estimated, and the next series of exposures timed accordingly. A sufficient variety of bacteria were tested to show that the action of the fluid was not limited to any special kind. The following table shows the results of the tests:²

Explanation: The first of the two figures stating time of exposure indicates the last positive culture, the second figure the first negative culture. The time is expressed in minutes, except in the case of the last two organisms.

Strength of solution computed in percentage gold chlorid	1/2 p. c.	1/3 p. c.	1/4 p. c.	1/8 p. c.	1/16 p. c.	1/32 p. c.
<i>Staphylococcus aureus</i>	1, 1	1/2, 1	2, 3	5, 8	8, 10	10, 15
<i>B. coli communis</i>	1, 1	..	1, 2
<i>B. typhosus</i>	1, 1	2, 4
<i>B. prodigiosus</i>	1, 1	1, 2
<i>Pneumococcus</i>	1, 1	..	1/2, 1	2, 4	4, 6	..
<i>Streptococcus</i>	1, 1	1/2, 1	1/2, 1	1/2, 1
<i>B. diphtheria</i>	1, 1	1/2, 1	1/2, 1	1/2, 1	2, 4	4, 8
<i>B. pneumoniae</i>	1, 1	..	1/2, 1	..	1/2, 1	..
<i>B. anthracis (spores)</i>	2, 3	..	3 1/2, 4 1/2
<i>B. subtilis (spores)</i>	2, 3	..	6, 10

2. These tests have been carefully repeated and the results confirmed by Dr. E. N. Toby in the bacteriological laboratory of the Harvard Medical School.

Bactericidal Action in Presence of Albumin.—A saturated filtered solution of dried egg albumin was mixed with the 1/2 per cent. solution in the proportion of 1:2, making the final percentage 1/3 per cent. and the mixture tested as described above. The *staphylococcus aureus* was selected for these tests on account of its resistant powers. The results obtained were practically the same as when the dilution was made with normal saline solution. When the tests were made immediately after mixing a slightly longer exposure was required, due no doubt to the fact that the solution did not have the same concentration throughout. The same thing was true when the organisms were stirred in the albuminous fluid first and the antiseptic then added. When the mixture was allowed to stand one hour before testing the results were exactly the same as in the absence of albumin. After standing twenty-four hours an exposure of two to three minutes was required. At the end of twenty-four hours the mixture began to assume a purple tint, indicating a reaction between the albumin and gold, and after several days a precipitate was thrown down. It is evident from these tests, therefore, that for all practical purposes the bactericidal action of the antiseptic is not interfered with by the presence of albumin.

Bactericidal Action in Presence of Urine.—On mixing with urine no apparent reaction took place and the bactericidal power of the antiseptic was not impaired even when the mixture was allowed to stand forty-five minutes before testing.

Bactericidal Action in Presence of Blood.—When the 1/2 per cent. solution was mixed with an equal quantity of blood the latter immediately became more intensely red and the bactericidal properties of the antiseptic were at once destroyed. The typhoid bacillus was not killed by the mixture after an exposure of twenty-four hours. Microscopic examination failed to show any change in the character of the blood on the addition of the antiseptic, but its power to coagulate was destroyed.

The prompt change in color of the blood and the simultaneous loss of bactericidal power point to a union of the gold with the hemoglobin of the blood. A reaction with the blood plasma is extremely improbable, owing to the extreme slowness with which the antiseptic reacts with albumin. In any case, these tests demonstrate the futility of attempting to use the antiseptic intravenously.

Bactericidal Action of Pus.—Pus obtained from cases of otitis media, infected with the *staphylococcus aureus* and *alb.*, was tested. Negative cultures after exposure of three to four minutes to the 1/2 per cent. solution.

Action of the Antiseptic on Ferments.—It was found that the pancreatic digestion of albumin was not interfered with in the 1/8 per cent. solution, but was prevented in the 1/4 per cent. solution. At the end of twenty-four hours the latter was diluted to make a 1/8 per cent. solution, but digestion still failed to go on, indicating destruction of the enzyme. The fermentation of glucose by yeast occurred in the 1/64 per cent. solution, but not in the 1/32 per cent. solution. Yeast exposed to the action of the 1/16 per cent. solution for one hour failed to ferment glucose when the mixture was diluted to the strength of 1/64 per cent.

TOXICITY OF THE ANTISEPTIC.

The harmlessness of the 1/2 per cent. solution when dropped into the conjunctival sac has already been mentioned. It has been used in this way at intervals of two minutes for one-half hour and at intervals of fifteen minutes for two weeks without injury to the eye. The subcutaneous injection of the fluid into a rabbit and also

into my arm was followed by no reaction. The following experiments were made to determine its remote effects when absorbed and taken into the circulation: Three c.c. of the $\frac{1}{2}$ per cent. solution were injected into the ear vein of a rabbit without producing any apparent effect. Fifteen c.c. of the same solution were injected into the peritoneal cavity of a rabbit weighing four pounds, also without apparent effect. This would be equivalent to a dose of about 500 c.c. in the case of an adult man. On the other hand, thirty c.c. of the $\frac{1}{2}$ per cent. solution injected into the peritoneal cavity of a rabbit weighing four- and one-fourth pounds caused death in twenty-one hours. The animal showed toxic symptoms within about five minutes after the injection, evidenced mainly by drowsiness, which gradually became more marked until death ensued. The abdominal cavity, opened immediately after death, was found perfectly normal and free from congestion. These experiments show that so far as the treatment of the eye is concerned no remote toxic effects of the antiseptic need be feared.³ It would seem also that the antiseptic could be used with safety in the treatment of genitourinary diseases. The effect produced by the absorption of large quantities of the antiseptic at frequent intervals requires further investigation.

PENETRATING POWER OF THE ANTISEPTIC.

That the effective penetrating power of the fluid is very great is indicated by its bactericidal power in the presence of albumin. The rapidity with which the fluid is absorbed was shown by the experiment just mentioned, in which thirty c.c. of the $\frac{1}{2}$ per cent. solution was injected into the peritoneal cavity of a rabbit. Here toxic symptoms were produced in five minutes, whereas fifteen c.c. similarly injected produced no effect, indicating in the former case great absorption in a short time.

COMPARISON WITH OTHER ANTISEPTICS.

The bacteriologic tests already given show the $\frac{1}{2}$ per cent. solution to be more powerful than a 1:1000 solution of mercuric chlorid. A few of the latter, made under the same conditions, showed that it required two to three minutes to kill *Staphylococcus aureus*. It was found that more bacteria were killed in a shorter time by the mercuric chlorid than by the antiseptic for a longer time. This is in accordance with the finding of Abbott that a few cocci may be killed after an exposure of thirty minutes to the 1 per cent. mercuric chlorid solution. Silver nitrate in 2 per cent. solution, which was once generally used in treatment of corneal ophthalmia, but now largely abandoned on account of its irritating qualities, requires between four and eight minutes to kill the *Staphylococcus aureus*. It is, moreover, precipitated by albumin and sodium chlorid. I found argyrol, the silver compound now most used for this purpose, to require, even in a freshly-prepared 50 per cent. solution, at least thirty minutes to destroy the *Staphylococcus aureus*. A 12 per cent. solution failed to destroy the same organism after an hour's exposure. Contrary to statements sent out by the manufacturers of this

preparation, I found that it was precipitated by albumin. When the 50 per cent. solution was mixed with an equal quantity of saturated albumin solution it failed to kill the *Staphylococcus* after an exposure of three hours, thus showing that it possesses no effective penetrating power. It was found also that argyrol was precipitated by urine. Spores of the hay bacillus were not destroyed by a 50 per cent. solution of argyrol after an exposure of twenty-four hours.

To explain how the antiseptic destroys bacteria is difficult. It seems most likely that the death of the bacteria is due to the replacement of some important radicle in their protoplasmic molecules by gold. This is suggested by the fact that metallic gold itself is antiseptic. Gold is so easily precipitated from the solution that it is almost as if the organisms were exposed to nascent gold. To explain why the solution will kill bacteria in less than a minute, while it requires hours to react with albumin, and to explain its harmlessness to the tissue cells, is also difficult. The first explanation that suggests itself is that the phenomenon is due to some peculiarity in the protoplasm of the bacteria. Possibly it is dependent, in part, at least, on the small size of bacteria. Thus if one micron is assumed to be the average diameter of a bacterium and twenty microns that of a tissue cell, the relative volumes of the two would be as 1:800. According to this ratio, if the bacterium was killed by an exposure of one minute, the tissue cell would require an exposure of about twelve hours. Moreover, it would seem that such a slow antiseptic action as this might be overcome by the vital activity of the cell.

In connection with this aspect of the subject, Dr. Henderson has made some observations, indicating a physical basis for the bactericidal action of the antiseptic, which he has kindly described in the following note:

PHYSICAL PROPERTIES OF THE ANTISEPTIC.

LAWRENCE J. HENDERSON, M.D.*

The solution described above, sodium aurate acidified with boric acid, in which the chemical equilibrium between the various constituents has not been determined, possesses two important properties which must contribute to the knowledge of its action on micro-organisms.

The one of these, which was investigated with the Overton-Hans Meyer theory of necrosis in mind, is the ability of the solution to give up gold to neutral olive oil when shaken up with that solvent. It was found in four experiments, on shaking together neutral olive oil and a solution of 0.7 per cent. of sodium aurate acidified with boric acid, separating the two phases in a separatory funnel and drying the oil with calcium chlorid, that the oil always contained gold, as was proved by heating the oil, thereby reducing the gold compound to metallic gold, which colored the liquid red. In the aqueous phase the gold was determined by precipitating it as sulphid and weighing the resulting metal. In all cases the amount of gold remaining in aqueous solution was markedly decreased 25 per cent., but variations in acidity of the solutions influenced the equilibrium of partition between the two solvents.

The significance of this solubility of gold in oil depends on the fact that the lipoids of the cell wall, lecithins, cholesterol, etc., manifest much the same solvent action as oil, so that in this case, as in the case of the narcotics, the penetration of the foreign substance into the cell is to be explained by a simple physical mechanism.

3. In connection with the application of antiseptic solutions to the eye I suggest what is believed to be a new method. This consists in building a sort of dam, as it were, around the eye, extending from the nose to the temple and as close to the eye as possible. As material for the dam, Dr. E. J. Hussey suggested the use of ordinary carpenter's putty, and in actual practice this has answered the purpose admirably. When the patient is reclining, and the small elstern formed in this way is filled with fluid (about 10 c.c.) not only the cornea and entire conjunctival sac are exposed to the action of the antiseptic but the lid margins and surrounding skin also.

* From the Laboratory of Biologic Chemistry of the Harvard Medical School.

The second significant fact is that this solution, almost ineffective itself to coagulate egg albumin, rapidly, and under proper conditions, completely coagulates that mixture of proteids, when reduced in its presence by ferrous sulphate or other substances. This was proved by mixing in three cylinders, 1, gold solution + egg albumin; 2, ferrous sulphate + egg albumin; 3, gold solution + egg albumin + ferrous sulphate.

In the first two cylinders a cloud appeared only on standing and did not become heavy for hours. In the third cylinder the gold was immediately and completely reduced, a voluminous precipitate resulted, and in a portion of the filtrate from this precipitate it was impossible to find albumin.

It has been shown by Dr. Verhoeff that bacteria which have been killed by this gold solution are colored with metallic gold. This intracellular reduction may be due to numerous factors, but oleic acid alone is enough to bring it about by a reaction analogous to the well-known osmic acid staining reaction. It is probable, as in the experiment described above, that within the cell during the reduction of the gold the cellular proteids are coagulated and the organism killed.

Special Article

THE PHYSICIAN AND THE PHARMACOPEIA.*

CHAPTER V.

DIURETICS.

Diuretics and diaphoretics may be considered together since they are often used for the same purpose, the one being used to supplement the other, and because the same agent which produces diuresis under certain conditions, may cause diaphoresis when these conditions are slightly changed.

Diuretics may be divided broadly into those which influence the circulation, and those which act on the secretory cells of the kidney. Though the same agent may possess both actions to some extent, we shall consider these remedies with reference to the principal effect according to this classification.

While the exact mechanism of urinary secretion remains a problem, the indications for diuresis and the method of causing it are fairly clear. When the official remedies fail to produce this effect we may usually attribute the failure to the condition of the kidney, feeling sure that the secretory cells are incapable of performing their function and that nothing short of the creation of new cells can be effective. Even this task would not be beyond the powers of some of the much vaunted mineral waters and nostrums if we are to believe the statements made in the circulars and other advertisements of the proprietors.

Diuretics are especially indicated in dropsy of cardiac, or even of renal, origin, provided the cells are capable of free secretion. In renal dropsy agents of the first class (those which influence the circulation), or those which mildly stimulate the kidney cells without producing irritation, are to be preferred. If the renal cells are incapable of increased secretion, diaphoresis should be resorted to in order to give rest to the kidneys.

Diuretics are also important in causing the removal of toxins and substances which form concretions (urates and phosphates).

Digitalis.

Nearly all authorities agree that digitalis is the most important of the official remedies in the treatment of dropsy of cardiac origin, its action being directed mainly toward the increase in the efficiency of the heart, with a consequently improved circulation in the kidney and increased diuresis. For this purpose the tincture is frequently employed, but, perhaps, the most efficient remedy is the combination of digitalis with squill and calomel, commonly called Niemeyer's pill.[†]

The official squill, which is described in Chapter II, is too irritant to permit of its employment in nephritis. This is very important and should be borne in mind if one uses any of the much-heralded diuretic nostrums which contain squill or its active principles.

That squill is extremely active in causing a watery diuresis is true, but in overdoses it is equally potent to lessen or even to suppress the flow by reason of its irritant action. This may result in bloody urine. This irritant action may serve to explain the "malaise" and some other ill effects resulting from the misuse of squill, or nostrums containing it, when it is specifically contraindicated.

The dose of squill, in powder, is 0.05 to 0.1 gm. (one to two grains) every three hours until some nausea occurs.

DIGITALIS.—U. S.—Digitalis, Foxglove. The dried leaves of *Digitalis purpurea* are collected from the second year's growth. First used for scrofula, its diuretic properties were discovered by Withering about 1775, when it leaped into popularity and is now official in all pharmacopeias.

Owing to the variability of the cheaper grades of digitalis, it is well to insist on the English or on a comparatively fresh leaf of the second year's growth.

There is much confusion in regard to the use of the terms digitalin and digitaline (not digitalein), but it is hardly advisable to consider the subject extensively in this place. Commercial digitalin, i. e., that found in the shops, consists of variable amounts of the active principles of digitalis. The term digitaline (not digitalein) is misleading and should be avoided. Digitoxin has recently been brought into prominence, but it is better to confine ourselves to the use of the powdered leaves and the official preparations, the latter being very commonly prescribed alone; indeed, there is still so much obscurity about the chemistry of digitalis that the physician will do well to avoid the use of any of the isolated active principles. It is to be remembered that the action of digitalis is elicited slowly, and that it is sometimes necessary to precede it with a more promptly acting drug, such as caffeine or strophanthus. The several preparations of digitalis are given at intervals of from four to six hours.

Their use in cardiac insufficiency will be discussed later.

Average dose: 0.05 gm. (50 mg. or 1 grain).

Of the preparations of digitalis the most desirable, when diuresis is the main factor, is:

INFUSUM DIGITALIS.—U. S.—This represents 1.5 per cent. of the leaves extracted with boiling water, flavored with cinnamon water and preserved with 10 per cent. of alcohol.

Owing to the development of principles with a picrotoxin action in the infusion which has been kept for a long time, it should be freshly prepared when dispensed.

Average dose: 8 c.c. (2 fluidrachms).

TINCTURA DIGITALIS.—U. S.—This is now of 10 per cent. strength instead of 15 per cent. as formerly.

Average dose: 1 c.c. (15 minims).

FLUIDEXTRACTUM DIGITALIS.—U. S.—This is made with diluted alcohol.

Average dose: 0.05 c.c. (1 minim).

EXTRACTUM DIGITALIS.—U. S.—This is made by evaporating the fluid extract to a pilular consistence.

*A typographical error occurred in the "typical ipecac prescription," in Chapter II of this article in THE JOURNAL, Dec. 23, 1905, page 1951. In the first column the amounts of ammonium chloride and syrup of iodo are not correct in the apothecaries' system, the drams and ounce signs having been transposed. Our attention was called to this early, but we considered the error so apparent that no physician would fail to recognize it, so we made no mention of it in THE JOURNAL. As correspondents continue to write about it, however, we call attention to the error and acknowledge their kindness in writing.

3. The formula for this pill is as follows:

R. Pulvis digitalis	
Pulvis scellæ, 55.....	grs. x
Hydrag. chlorid. mlt.	grs. 10
This amount is to be divided into ten pills, or preferably, capsules. One of these pills every three hours will be found effective. The calomel is often omitted, or it may be replaced by 0.06 gm. (1 grain) of the blue mass (massa hydragryi) in each dose, if it is to be made into pills, or may powder (hydrargyrum cum creta), if into capsules.	

Average dose: 0.01 gm. (10 mg. or 1/5 grain).

Strophanthus.

Rather closely resembling digitalis in its action on the heart and as a diuretic, if indeed, it may not surpass the older drug in the latter case, is strophanthus, which does not cause the same degree of vasoconstriction which sometimes interferes with or prevents the diuretic action of digitalis. It is mostly used in the form of the tincture.

While strophanthus has some advantages, such as the more prompt action and a slighter tendency to cause cumulative effects, clinicians have not found it so generally useful as digitalis.

The powerful action of strophanthin as a local anesthetic, though denied, has been well established.

STROPHANTHUS.—U. S.—The ripe seed of *Strophanthus komé*.

TINCTURA STROPHANTHIL.—U. S.—This is now of 10 per cent. strength—just double that formerly official.

Average dose: 0.5 c.c. (8 minims).

STROPHANTHUM.—U. S.—This consists of one or more glucosides on which depend the medicinal properties of strophanthus.

Average dose: 0.0003 gm. (0.3 mg. or 1/200 grain).

Apocynum.

APOCYNUM.—U. S.—This drug has enjoyed a considerable reputation in domestic practice as a remedy in dropsy, but appears to be inferior to digitalis in the same group to which it belongs.

H. C. Wood, Jr., believes that this drug deserves more attention as a cardiac stimulant than it has hitherto received.

It is not used in substance; instead its liquid preparations are used.

FLUIDEXTRACTUM APOCYN.—U. S.—This is the only official preparation.

Average dose: 1 c.c. (15 minims).

Caffein.

When cardiac stimulants or other agents cause such vasoconstriction as greatly to lessen the amount of blood which passes through the kidney, and consequently the diuresis, a vasodilator is sometimes employed, but it is more rational to avoid the necessity for this when possible.

When the object of diuresis is to get rid of fluid which has accumulated, it is, of course, better to avoid unnecessary amounts of water, and in such cases diuretics are given in solid, or at least concentrated, form.

Caffein is the most prominent of the official drugs which produce diuresis mainly by action on the kidney cells. While digitalis may act slightly on the kidney cells, but mainly on the heart, caffein, on the other hand, acts mainly on the cells of the kidney and much less on the heart. It may, however, cause such considerable vasoconstriction as seriously to lessen the amount of blood passing through the kidney and the diuresis in consequence, in that case the unofficial theobromin might be employed, as this is said to interfere much less with the circulation. Dr. G. N. Stewart states that caffein causes a passing vasoconstriction in the kidney with lessened diuresis, soon followed by vasodilation with increased diuresis.

When cerebral excitement (a tendency to wakefulness) is to be avoided, caffein is contraindicated.

Caffein is a constituent of tea, coffee, kola, and more abundantly (5 per cent.) of guarana, which is official.

Caffein is not very soluble in water or alcohol, but its solubility in water is greatly increased by such salts as potassium bromid, and sodium benzoate or salicylate; this well-known fact has been appropriated as a "discovery" by manufacturers of certain nostrums.⁴

CAFFEINA.—U. S.—This is a feebly basic (alkaloidal) substance obtained from *Thea sinensis*, *Coffea arabica* or other plants. It does not form stable salts.

Average dose: 0.05 gm. (50 mg. or 1 grain).

Two other soluble forms of caffein are:

CAFFEINA CITRATA.—U. S.—This consists of equal parts of caffein and citric acid.

Average dose: 0.1 gm. (2 grains).

CAFFEINA CITRATA EFFERVESCENS.—U. S.—This contains 4 per cent. of citrated caffein.

Average dose: 4 gms. (60 grains).

Diuretin is a mixture of theobromin and sodium salicylate, while agurin consists of theobromin, sodium and sodium acetate. Mixtures of caffein and lithium benzoate or salicylate are also used. Diuretin is decomposed on exposure to the air and becomes much less soluble.

When caffein or other diuretics produce a more than temporary vasoconstriction in the kidney, one drop of the 1 per cent. solution of nitroglycerin may be given at the same time.

The usefulness of hot tea as a diuretic is too well known to require further comment.

The official sugar of milk and the unofficial urea cause diuresis, probably by acting on the renal epithelium.

Scoparius.

SCOPARIUS.—U. S.—This is sometimes incorrectly classed with digitalis because it slows the heart, but it weakens the beat while digitalis strengthens it. The alkaloid, spartein, is responsible for the cardiac and vasoconstrictor effect of scoparius, but the diuretic effect is due to scoparin, a glucosid.

Average dose (of scoparius): 1 gm. (15 grains).

The infusion or decoction is recommended for producing diuresis, except in dropsy.⁵

Spartein.

SPARTEIN SULPHATE.—U. S.—While this is obtained from scoparius it is not a diuretic.

Average dose: 0.01 gm. (1/5 grain), but this dose is sometimes considerably exceeded.

Irritants.

Irritants which are excreted by the kidneys produce diuresis but, of course, they must not be used in greater amounts than are necessary to produce a mild stimulation. They are contraindicated in nephritis.

The use of calomel in connection with squill and digitalis has been mentioned. It is most useful in cardiac dropsy and its use is to be stopped when the diuresis becomes free. It may be given in doses of 0.2 gm. (3 grains) three times daily, or in the form of Niemeyer's pill.⁶

Volatile Oils.

The irritants include a number of volatile oils which are much more frequently used for their antiseptic action on the urinary tract than for any slight increase in renal action which they may cause. They include such volatile oils as oil of turpentine (oleum terebinthinae) and oil of juniper (oleum juniperi), which are more often used as diuretics than copaiba, cubeb and matico, which are employed mainly as antiseptics.

Hexamethylenamin.

The volatile oils have been largely superseded as urinary antiseptics by the now official synthetic hexamethylenamin.⁷

HEXAMETHYLAMIN.—U. S.—(Hexamethylen tetramin.) This is a condensation product produced by the union of formaldehyd and ammonia. While free from the irritating effect of formaldehyd it yet retains its antiseptic properties, the formaldehyd being gradually set free by dilute acids, etc. Being an ammonium derivative, a solvent effect on uric acid, etc., has

⁴ The following mixture, to be varied according to needs, represents the method of using caffein in this soluble form:

Caffein (alkaloid) 4
Sodium salicylate, 5% 31

Chinamon water to make 100

Each teaspoonful contains about 0.2 gm. (3 grains) of caffein. Sodium benzoate or lithium salicylate or benzoate may be substituted for the sodium salicylate. This formula requires no unusual pharmaceutical skill to compound and the cost is very much less than that of the proprietary used for the same purpose.

⁵ Scoparius
Potassium Bitartrate, 5% 388 15

This quantity of material is to be added to 1 liter (1 quart) of water, in a suitable vessel, boil for ten minutes. Allow to cool and strain. A wineglassful of the resulting decoction may be given every hour.

⁶ The official name is very cumbersome, but no satisfactory substitute has thus far been suggested. Hexamethylenamin was first brought before the profession by Schering under the trade name of urotropin (Schering and Glatz), and it is still sold by them under this name. It is also on the market under various other trade names, such as aminoform, formin, cystogen, and others.

been claimed for it, just as for lithium salts. It is readily soluble in water and is best given in solution.

Average dose: 0.25 gm. (4 grains).

This substance has been introduced with some slight modification under various names; usually the modification is only sufficient to enable the manufacturers to say that their product is not identical with the official. For instance, helmitol is anhydromethylen citric acid with hexamethylenamin. Uriform embraces two other drugs of minor importance. The official preparation may be considered at least equal to them, since it is not modified by any useless or inferior products, and is readily controlled by chemical tests for purity.

Uva Ursi.

Another drug of this class which has been the subject of much dispute is uva ursi. Its principal usefulness is probably in catarrhal conditions of the urinary tract. It contains a glucosid, arbutin, which is decomposed, partly perhaps in the kidney, but more abundantly in contact with catarrhal mucous membrane, hydrochinon, an antiseptic, being formed.

UVA URSL.—U. S.—The dried leaves of *Aretostaphylos uva ursi*, of which the only official preparation is:

FLUIDEXTRACTUM UVA URSL.—U. S.

Average dose: 2 c.c. (30 minims).

Infusion of uva ursi is made according to the general formula for infusions by pouring 1 liter (1 quart) of boiling water on 50 gms. (1 oz. 5 drs.) of bruised uva ursi.

The fluid extract or the infusion may be given alone three or four times daily.

Chimaphila.

CHIMAPHILA.—U. S.—The dried leaves of *Chimaphila umbellata*, commonly called pipsissewa. It was introduced in America by Dr. John S. Mitchell in 1803, and later into England.

Its medicinal action closely resembles that of uva ursi, to which, however, chimaphila is inferior.

FLUIDEXTRACTUM CHIMAPHILAE.—U. S.

Average dose: 2 c.c. (30 minims).

Acetates and Citrates.

There remains to be considered an important class of substances, which are used as diuretics, but they are so well known that only a very brief notice is needed here.

The acetates or citrates of sodium and potassium increase the alkalinity of the blood and lessen the acidity of the urine or render it alkaline; they also increase diuresis. Potassium bitartrate and nitrate are also widely used as diuretics, mainly as additions to mixtures. For this purpose they are largely diluted with water, the latter alone being the most commonly used of all diuretics.

Cantharides is very rarely used for its effect on the kidneys, as it is extremely irritant.

The methods used for producing diaphoresis are analogous to those employed for diuresis, consisting in those which influence the circulation and those acting on the sweat glands; but in addition, certain agents, notably, solution of ammonium acetate, act on the sweating center.

The circulation in the skin is readily influenced by the application of heat in numerous ways and by what amounts to the same thing, the prevention of its loss by an impervious cover, such as oiled silk or by agents which cause dilation of the vessels of the skin, such as hot alcoholic drinks and spirit of nitrous ether. Everyone is familiar with the sweating of nausea, and while any nauseant will cause diaphoresis, the only one which is generally employed for the purpose is the powder of ipecac and opium, the well-known Dover's powder. The only official substance used for the purpose which directly stimulates the secretion of sweat is pilocarpus and its alkaloid, pilocarpin. They do not act on the secretory cells as caffeine does or on the kidney, but by stimulation of the secretory nerves.

Diaphoresis are employed to arrest "colds" in the early stages, to aid in getting rid of fluid accumulations, as in dropsy, and to a lesser extent for getting rid of excretions. Diaphoresis often serves to relieve the kidneys or to supplement their action. Vegetable infusions which cause diuresis

will usually cause diaphoresis at the same time if the patient is kept warm and measures are taken to increase the blood supply of the surface (rubbing, mustard, etc.).

For the arrest of "colds" nearly anything causing sweating seems to be effective, but the powder of ipecac and opium mentioned in Chapter II enjoys a particular reputation.

PULVIS MORPHINÆ COMPOSITUS.—U. S.—Compound powder of morphin, also known as Tully's powder, containing 1.5 per cent. of morphin and 32 per cent. of camphor, has also been recommended, and is sometimes used, as a diaphoretic, in place of the older and more popular Dover's powder.

Average dose: 0.5 gm. (7 grains).

Potassium citrate, referred to as a diuretic, is much used for its diaphoretic effect, particularly in the form of:

LIQUOR POTASSII CITRATIS.—U. S.—This is a water solution of potassium citrate, containing about 8 per cent. of anhydrous potassium citrate.

Average dose: 15 c.c. (4 fluidrachms).

SPRITUS ÆTHERIS NITROSI.—U. S.—Sweet spirits of niter. This is a very generally popular diaphoretic which is also used as a diuretic in fevers.

Average dose: 2 c.c. (30 minims).

LIQUOR AMMONIÆ ACETATIS.—U. S.—The old-time spirit of Mindereus.

Average dose: 15 c.c. (4 fluidrachms).

Pilocarpus

The only official drugs which have diaphoresis as their predominant therapeutic action are pilocarpus and its alkaloid, pilocarpin. They are both too well known to require very extended notice in this place.

PILOCARPUS.—U. S.—Pilocarpus or jaborandi leaves contain, by assay, not less than 0.5 per cent. of alkaloids.

Average dose: 2 gm. (30 grains), given occasionally in the form of a 5 per cent. infusion, made according to the official general formula for that class of preparations.

FLUIDEXTRACTUM PILOCARPI.—U. S.—This is made with diluted alcohol and contains 0.4 per cent. of the alkaloids from pilocarpus.

Average dose: 2 c.c. (30 minims).

PILOCARPINÆ HYDROCHLORIDUM.—U. S., and
PILOCARPINÆ NITRAS.—U. S., are therapeutically identical. They are both very soluble in water.

Average dose of either: 0.01 gm. (1/6 grain).

Clinical Report

A CASE OF CARCINOMA OF THE PANCREAS.

WITH NEGATIVE SO-CALLED PANCREATIC REACTION:

CHOLECYSTENTEROSTOMY.

JOHN C. HANCOCK, M.D.

Surgeon to Finley and St. Joseph's Mercy Hospitals.

DUBUQUE, IOWA.

In a series of 53,000 cases of carcinoma collected from European institutions, in which careful postmortem records are kept, there were 226 cases of carcinoma of the pancreas, or 4.2 cases in every 1,000 cases of carcinoma of all organs. In the following case, in spite of repeated trials and a positive diagnosis, the so-called pancreatic reaction of Cammidge was negative. In the course of an exploratory laparotomy cholecystenterostomy was performed to relieve distress from absorption of bile and pain due to pressure of distention of the bile tract and accomplished the purpose.

Patient.—D. A., farmer, 58 years old, married, born in England, residence Bloomington, Wis., was referred to me June 26, 1905, by Dr. J. M. Lewis of the same place.

Family History.—Negative, except that his father died of "stomach trouble."

Previous History.—In this the only conspicuous features are sciatic rheumatism, so-called, from time to time for several years and previous to ten years ago, excessive use of alcohol. Patient denies venereal disease.

Present Illness.—This seems to date back two and one-half years to an accident whereby he was thrown from a wagon and struck on back of neck and small of back. Following the accident and lasting for two months there was paralysis of both upper extremities. This cleared up spontaneously. The bowels, previously naturally regular, have not moved since without the aid of drugs, and this condition has been getting progressively worse. His best weight five and one-half years ago was 200 pounds and at the time of accident was 175. Whereas patient dates the beginning of his illness with the occurrence of the accident, his present condition probably really began to manifest itself in December, 1904. At this time patient weighed 170 pounds, and since then his weight has progressively fallen to 130. With this rapid decline in weight his strength, too, began to fail and has kept pace with the loss of weight. Accompanying the constipation which followed the accident indigestion began, but it was not until December, 1904, that this became more than ordinarily marked. In March, 1905, dyspeptic symptoms became pronounced. These consisted of loss of appetite, especially for meats; distress after eating, with belching, water brash and nausea. In April, 1905, pain began in the right upper quadrant of the abdomen, extending downward on the right side of the abdomen, around the lower ribs on the right side to the back and across the upper half of the abdomen. The character of the pain varied from a dull ache, which was almost constant, to severe paroxysms of acute pain. The pain was remarked to be worse at night. Further, the pain was aggravated by constipation and relieved by catharsis. At this time patient detected a lump in the upper right quadrant of the abdomen. Early in May bronzing of the skin set in. Toward the end of May, without regard to pain, vomiting began. This occurred especially after meals and also before breakfast. For the last two weeks patient has vomited in the evening what was eaten during the day. One week ago jaundice set in insidiously and has become rapidly and progressively deeper. Considering the amount of food eaten, the stools were noticeably bulky and contained undigested food particles. Fat in the stools was not remarked, and there has been no diarrhea. Since the jaundice set in the stools are lighter in color and the patient has felt weaker. The bronzing of the skin has also been obscured by the jaundice. The patient was alarmed about his condition by the pain and the on-set of jaundice.

Examination.—The patient was a man of six feet or more, well developed but poorly nourished. The skin and conjunctive were deeply pigmented with bile, but no subcutaneous hemorrhages were made out. The history of the accident was borne out by a well-marked kyphosis in the mid-cervical region. Here, instead of a convexity forward, there was a convexity backward of the fourth, fifth and sixth cervical vertebrae. The thorax was negative. Bilateral inguinal, and saphenous, and right supra-clavicular lymphatic glands were moderately enlarged, firm, smooth, movable, discrete and not tender. Knee jerks were present, but feeble. There was no edema of the ankles. Per rectum prostate and adnexa were negative, as also were the external genitals. Pulse was 72, temperature 99 and respiration 20. The abdomen on inspection revealed the light and shadow of a mass in the upper half of the abdomen. Pulsation over the mass was visible. On palpation a large, smooth, firm mass, nodular on a large scale, was made out extending across the abdomen almost from rib to rib, the lower border being on a level with the umbilicus. The mass was but slightly movable and tender on deep pressure only. Immediately around and behind the umbilicus deep resistance was made out merging above with that of the mass mentioned. The mass measured roughly seven inches across by three inches vertically. It was greater in the antero-posterior and vertical planes on the right side of the median line. Pulsation of the mass was marked. Above the mass there was an area of resonance filling the epigastrium and extending particularly to the left behind the ribs. On the right the outline of the mass was less distinctly followed along the costal margin down

ward. The liver dullness extended from the fifth rib to one finger's breadth below the costal margin in the mammillary line. Opposite the ninth rib, beneath the liver, could be indistinctly felt a large, smooth, rounded mass about the size of a small orange, fading away above and to the left into the larger mass. This evidently represented the gall bladder. On bimanual palpation the right kidney was found negative, likewise the spleen. No ascites was made out. On dilatation of the stomach with air resonance was found over the epigastrium extending upward behind the xyphoid cartilage and well to the left behind the ribs. Below this area of resonance the mass remained immovable and unaffected by respiration and manipulation. At the same time the tumor mass seemed to be near the anterior abdominal wall, dividing the cavity into upper and lower sections, the upper having the stomach resonance and the lower that of the colon and small intestines. The floor of the upper section on deep palpation seemed to have a shelving surface, with the dilated stomach more superficial than the mass.

Fluid dilatation showed the stomach capacity to be forty-six ounces. After a test meal of toast and tea the stomach contents gave a negative reaction to litmus, no free HCl, and a positive reaction to lactic acid. With air dilatation the stomach orifices leaked perceptibly. Urinalysis gave sp. gr. 1.007, faintly acid reaction, slightest possible trace albumin, no sugar, bile present, indeterminate sediment, and negative so-called pancreatic reaction.

The patient was told frankly that in all probability he had a malignant growth, that it was either in the stomach or in the pancreas, that an operation would probably be of no permanent and perhaps of no temporary benefit, but that an exploratory opening of the abdominal cavity would settle the diagnosis and might suggest an operation for relief of some of the symptoms. With this understanding the patient requested the operation, and asked to have done whatever was indicated in the premises.

Operation.—Accordingly the abdomen was opened June 28 by an incision through the right rectus near the median line above the umbilicus. The stomach was found normal, but pushed upward by the mass. The pylorus was normal. The colon and omentum were found normal. These were brought out of the wound, revealing the enlarged pancreas stretching across the posterior wall and extending well to the left of the spinal column. The gland was greatly enlarged, especially on the right, hard and nodular. On the surface of the mesocolon and adjacent coils of intestines were numerous small, pearly, opaque, hard, nodules, irregular in size and shape. These with the enlarged retroperitoneal lymphatics accounted for the deep resistance on palpation about the umbilicus. Specimens of these nodules were removed and proved on histologic examination to be medullary carcinoma. To the right the gall-bladder was found distended to the size of the bulb of a three-ounce ear syringe. It was soft, but not easily compressible. The cystic, hepatic and common ducts were distended to the size of the little finger. No stones were made out. The head of the pancreas was greatly enlarged, and a process of the gland surrounded the junction of the common duct and duodenum. This process passing around to the right from behind the duodenum almost reached the main body of the head on the left and constricted the lumen of the duodenum.

Realizing that the situation was hopeless for cure and that the common bile duct was completely occluded, while the lumen of the duodenum was only constricted and would probably remain patent till death from intoxication and starvation occurred, I concluded to do cholecystenterostomy. This was done with a Murphy button at the hepatic flexure of the colon. Patient rallied from operation well. His pain, he said, was much less, and by the third or fourth day jaundice had practically disappeared. His appetite began then to improve and his mind became more active.

Subsequent History.—He returned home the twelfth day after operation, relieved of the jaundice and much of his pain. He is reported to have died August 13 and to have suffered severe pain the last few days. During the time after operation pancreatin was administered after eating with benefit to digestion.

In view of the reliance placed on the so-called pancreatic reaction of Cammidge¹ by Robson² undue weight was given to the negative result before operation in the diagnosis. This feature and the greater frequency of carcinoma ventriculi seemed to favor, on the doctrine of chances, cancer of the stomach with adhesions and extensions involving the common bile duct and immobilizing the mass. After the diagnosis became established further tests were performed before and after jaundice disappeared. All the tests were uniformly negative, in spite of care in following the author's directions and the use of reliable reagents. Instead of the characteristic crystals a brownish amorphous deposit was obtained. It is not my intention to impeach the value of the reaction, but rather to enter a plea for more light on the subject to the end that the reaction which Robson has found of signal value in this difficult class of cases may be made susceptible of general application.

Cholecystenterostomy has been held by many to be a questionable procedure in this class of cases, offering but slight benefit at the expense of some hazard and the usual discomfort following the operation. In the case in question the toxic symptoms of bile absorption and much of the pain—a large share of which seemed to be due to pressure from the distended bile tract—were

come plugged, thereby necessitating the removal of the tubes with the sutures and packing from the perineal wound, led me to experiment with metallic tubes, resulting in the instrument described below, which in my hands has proved very satisfactory. The tube for continuous irrigation is 12.5 cm. long, the size of a No. 32 French catheter. It is composed of a larger tube into which a smaller one is incorporated. At the vesical end are two openings, the larger being the outflow, the smaller the inflow. At the distal end the tube diverges, the larger one being attached to a drainage tube that is carried to a bucket under the bed; the smaller for the attachment of the tube from a fountain syringe, which is suspended two or three feet above the patient. After the tube is inserted it is held in place by a movable steel collar, controlled by a thumbscrew. Attached to the sides of the collar are two small rings, through which are passed the retention sutures from the perineal wound. By loosening the thumbscrew the tube can either be pushed farther in or drawn out without disturbing the dressings. If the tube becomes occluded it is very easy to remove it through the collar and replace it again in the bladder without disturbing the packing in the perineal wound. Until this instrument was devised I used two catheters stitched together, as advised by Dr. Young of Baltimore.

If the bladder is badly infected the irrigations are kept up for four or five days, or even longer; if not infected the continuous irrigation is stopped as soon as the fluid from the bladder comes away free of blood.

relieved. In view of the comparatively slight post-operative reaction the patient stated, on having the question put squarely to him, that he considered it worth the discomfort to obtain a definite diagnosis and be relieved of the worst of his suffering as long as might be.

New Instrument

METALLIC TUBES FOR CONTINUOUS IRRIGATION AFTER PROSTATECTOMY AND FOR DRAINAGE AFTER PERINEAL SECTION.*

FRANCIS R. HAGNER, M.D.

Clinical Professor of Genito-Urinary Surgery, George Washington University, and Attending Genito-Urinary Surgeon Garfield Memorial Hospital, WASHINGTON, D. C.

The difficulty often encountered in introducing the rubber tube after perineal prostatectomy, especially if the prostatic urethra is injured, as well as the tendency of the tube to be-

come plugged, thereby necessitating the removal of the tubes with the sutures and packing from the perineal wound, led me to experiment with metallic tubes, resulting in the instrument described below, which in my hands has proved very satisfactory. The tube for continuous irrigation is 12.5 cm. long, the size of a No. 32 French catheter. It is composed of a larger tube into which a smaller one is incorporated. At the vesical end are two openings, the larger being the outflow, the smaller the inflow. At the distal end the tube diverges, the larger one being attached to a drainage tube that is carried to a bucket under the bed; the smaller for the attachment of the tube from a fountain syringe, which is suspended two or three feet above the patient. After the tube is inserted it is held in place by a movable steel collar, controlled by a thumbscrew. Attached to the sides of the collar are two small rings, through which are passed the retention sutures from the perineal wound. By loosening the thumbscrew the tube can either be pushed farther in or drawn out without disturbing the dressings. If the tube becomes occluded it is very easy to remove it through the collar and replace it again in the bladder without disturbing the packing in the perineal wound. Until this instrument was devised I used two catheters stitched together, as advised by Dr. Young of Baltimore.

The advantages of continuous irrigation in these cases are: 1. The coagulation of the blood from any hemorrhage that may take place in the bladder and occlude the tube, as occurs in a tube without continuous irrigation, rarely occurs. 2. The liability to sepsis is lessened. 3. The patient is comfortable and does not have to be disturbed by irrigations.

The instrument for perineal drainage, where continuous irrigation is not indicated, consists of a tube 12.5 cm. long, the size of a 30 French catheter, with four openings in the vesical end (Fig. 1). The distal end has a shoulder to hold the rubber tube, which passes into the drainage vessel. The tube is held in the perineal wound by the collar as described in the instrument for continuous irrigation. The drainage through this tube is excellent, as the caliber is large and easily cleaned by irrigation.

My experience with both these tubes covers a number of cases in all of which the results were more satisfactory than with any other form of drainage tubes which I have used.

Opium in Australia.—The various Australian states having agreed to prohibit the sale and growth of opium, the government of the commonwealth has prohibited the importation of opium except for medicinal purposes. All the states will lose revenue by the prohibition, the loss to Queensland alone, it is said, being estimated at \$80,000 yearly.

THE ETIOLOGY OF GALLSTONES.

The activity in bacteriologic investigation which characterized the eighties of the last century led to numerous discoveries and numerous mistakes. Diseases which by analogy ought to have been bacterial were stated to be due to organisms which were afterward shown to be contaminations, and, on the other hand, diseases which at first sight seemed far removed from bacterial action were shown to be intimately associated with micro-organisms. Among the conditions which were investigated at this time were those associated with the formation of salivary calculi, and Galippe, who cultivated bacteria from these concretions, not only assumed a causal relation between the germs and the calculi, but predicted that other forms of calculi would be shown to be of bacterial origin.

So far as the bacterial origin of gallstones is concerned, it was Naunyn who first gave his unreserved support to this view of their origin. The view was not, however, generally accepted, for some observers took the ground that the presence of gallstones favored biliary infection and denied that the infection was the primary process and responsible for the formation of gallstones. The mere presence of bacteria, even in the interior of gallstones, was clearly not proof that the bacteria caused the stones, and it became more and more obvious that the matter could only be cleared up by the experimental method. The early experiments were many of them unsuccessful, though Gilbert and Fournier obtained an experimental stone in a dog as early as 1897. Since then a large number of studies have been made, mainly by the French school, and in a considerable number of instances experimental gallstones have been produced.

The rôle played by various factors in the stone formation has been recently reviewed by Lartigau¹ in a valuable paper, in which he also records the result of a large series of personal experiments. The main opponents of the bacterial theory of gallstones have maintained that the process of their formation was mechanical and due to the presence in the gall bladder of foreign material. Various studies, including those of Lartigau, have shown that the mere presence of an aseptic foreign body does not suffice to produce gallstones. The introduction of pieces of cotton, fragments of human calculi, grains of wheat and other irritating substances

does not lead to calculus formation even when the outflow of bile is partially obstructed. On the other hand, the introduction of bacteria associated with mechanical irritation of the mucosa is followed in a considerable percentage of cases by the formation of stones. If at the time that bacteria are introduced the outflow of the bile is interfered with, or aseptic foreign bodies are also put into the gall bladder, the chances of stone formation become much greater. Thus of nine rabbits inoculated by Lartigau in which the outflow of bile was partly obstructed when the bacteria were introduced eight developed stones, and almost as high a percentage of successes resulted from the introduction of foreign bodies with the bacteria.

The mode of action of bacteria in producing gallstones is still obscure. The chronic cholecystitis which they produce is associated with desquamation of epithelium, and this in turn favors the formation of cholesterolin and bilirubin-calcium. In many instances, however, this cholecystitis is not followed by the formation of stones, and some other factor must be present. It is probable that in some cases, as Cushing suggested, clumping of the bacteria may be an important preliminary step, the clumped bacteria acting as nuclei for the stones.

The point of entrance of the bacteria into the gall bladder has, until recent date, been usually regarded as the common duct. It seems natural to assume that with a relatively large channel directly connecting the gall bladder and the intestines this should serve as a carrier of bacteria. It is probable that in many instances the infection takes this route, though the importance of ascending infection at most has certainly been overestimated. The fact that in many instances gall bladder infections are due to bacteria not usually found in the duodenum is against ascending infection, and there is positive experimental evidence that bacteria introduced into the general or portal circulation may be recovered from the gall bladder; indeed, some organisms persist there when they have long disappeared from other parts of the body. Of course, there are many instances in which individuals with gallstones give no history indicating that they have ever had a general or even a severe intestinal infection, but these cases may be explained by Adami's theory of latent infection, according to which even healthy intestines allow the passage of bacteria into the portal circulation and thence into the gall bladder.

SOME FALLACIES OF VITAL STATISTICS.

Thé bewilderingments that lie in the path of the wanderer in the field of statistics have long served to edge the point of the jest that statistics can be made to prove anything. One witty essayist, in an article on "How to Know the Fallacies," thus delivers himself regarding the care necessary for raising these thrifty plants: "Statistics are recommended for a mulch. By covering a bed of fallacies with a heavy mulch of miscellaneous sta-

¹ Cal. State Jour. of Med., January, 1906.

tistical matter it is protected from the early frosts and the later drought. The ground of the argument is kept thus in a good condition. No particular care is here needed in the application of statistics; any man who can handle a pitchfork can do all that is required. I have seen astonishing results obtained in this way. No one need be deterred by the consideration of expense. In these days statistics are so cheap that they are within the reach of all. If you do not care to use the material freely distributed by the government you can easily collect a sufficient amount for yourself." Nowhere, perhaps, do fallacies spring up more abundantly and mistaken inferences flourish more rankly than when mulched with vital statistics. Inaccuracies in the collection of facts and misjudgments in the interpretation of those facts are not always easily detected, but may serve to vitiate many far-reaching conclusions and to cast doubt on not a few cherished doctrines.

Consider, for example, the use often made of the "death rate" of a community in basing comparisons of relative healthfulness and in furnishing a text for poems on sanitary progress. How much do we really know about it all? An elaborate analysis of the available data is not necessary to reveal the presence of difficulties. In the first place it has been often pointed out that the mere ratio of deaths to the total population can have little significance, since the ratio is obviously and profoundly affected by the number of persons of different ages in the population and by the proportion of the sexes. If this be so, of how much less value must be any conclusion as to the healthfulness of a population drawn from the mean age at death? Such information as most American communities possess concerning the age distribution of their population is derived solely from the returns of the decennial census and is doubtless of varying value, not only at different times, but in different places. Even in this apparently simple matter it does not seem to be easy to obtain accurate figures, and the precise age distribution of most American city populations is far too largely a subject of conjecture. Assuming, however, that it is possible to substitute for the "crude death rate" one corrected for age and sex distribution, obstacles immediately arise to prevent us from accepting the corrected rate as a measure of sanitary well-being. The varying preponderance of certain nationalities, as Irish, Italian, Scandinavian and Slav, in urban populations is one of the factors that undoubtedly affects death rates entirely apart from any wholesomeness of environment or efficiency of sanitary organization. At present the influence of race on death rate can not be evaluated in any precise fashion.

Another factor that will occur to many physicians is the influence that birth rate must have on death rate. A steadily declining birth rate is in itself sufficient to produce a declining death rate, and unless the facts in regard to the birth rate are known it is impossible to interpret correctly a decline in the death rate, or even in some cases to compare the corrected death rates to dif-

ferent localities. Now, it is a notorious fact that except in certain limited districts in this country, births are reported very irregularly and incompletely and data as to birth rate for any considerable number of years are lacking. There is, of course, reason to believe that even in those parts of the United States where no full record exists the birth rate has declined in the last few decades in common with the decline that has occurred in other parts of the civilized world. How, then, disentangle a reduction in a city death rate due to diminishing births, to change in character and amount of immigration and like factors, from a reduction due to the enforcement of sanitary regulations or to improvement in conditions in life? The problem is extraordinarily complex. We need first of all much fuller and more accurate data. Until these are secured a certain hesitancy, or, indeed, an ultra-conservatism, in drawing conclusions will perhaps best commend our discretion to posterity.

MEDICAL SUBJECTS ON THE STAGE.

Medical subjects on the stage was the theme of an inaugural thesis by J. Descout of Paris. In commenting on it, the *Semaine Médicale*, December 6, quotes the long final summary entire and states that the stage offers a powerful means of producing a profound impression on the public. Rich and poor attend the theaters and absorb ideas there which would never reach them if presented in any other form. Physicians have tried to educate the public in certain medical matters by published articles, by lectures, etc., but books are expensive, and lectures reach but a limited audience. The masses are not reached, and the zeal and activity of the medical apostles are wasted in great measure. This is why the results obtained by dramatists who have taken up this new line of presenting medical subjects have been so striking.

Descout reviews the various plays which have been staged in late years bearing on medical topics, and studies the influence exerted by them. He remarks that such plays as *Camille*, *l'Aiglon*, etc., only refer incidentally to disease to render their characters more interesting, but Ibsen's works, illustrating the influence of heredity, are written with incomparable art, both from the scientific and from the dramatic point of view. "Henriot" is the pseudonym of one of the members of the Paris faculty of medicine, and his play of "Enquête" portrays an epileptic of the masked and criminal variety. The dramatic art of this fine piece is equal to its scientific precision. In the play of "La Nouvelle Idole," de Curel debates whether or not a physician has the right to experiment on a living human subject and whether a scientist should or should not be at liberty to use hypnotism. "Baillon," by Le Senne and Mayer, turns on the false and painful situations in which physicians are frequently placed by strict observation of professional secrecy. These medico-psychologic plays differ from the medico-social dramas of Brieux and

Bruyerre. These writers took up purely medical subjects, not merely medico-literary or medico-ethical questions. Social hygiene, professional and private, was presented on the stage in a form calculated to impress the crowds, calling attention to deplorable conditions and starting an impulse for their reform. Brieux portrayed in his "Avariés"—the "Damaged"—the havoc wrought by syphilis in families, and in his "Remplacantes" the danger for the nurse of a syphilitic infant. He took great pains to have the scientific part of his plays correct, and cites his medical authorities in his published work.

The question whether or not such subjects do more harm than good on the stage is answered by Descoust decidedly in favor of the benefits to be derived from such a propaganda. Following Brieux's plays police regulations were enacted for the better protection of wet-nurses, and several special crèches for syphilitic children were founded by private charity. Following his play of "Maternité," associations were organized to enable women to be delivered in their homes. The organization of the Society for Sanitary and Moral Prophylaxis is also ascribed in large part to the influence of Brieux's "Avariés." The society has recently arranged a special dispensary service for syphilitics evenings and Sunday mornings, so that these unfortunates can have regular treatment which will not encroach on their working hours. Bruyerre's play "En Paix" was suggested by the incarceration in an asylum of a pseudo-insane friend. The play resulted in his liberation and a reform in the law on the subject is now under consideration.

The argument has been raised that medical subjects on the stage are an offense against public morality. Descoust asserts, however, that it can do no harm to recite what it is regarded as useful to write. In conclusion, he reiterates that the stage is a powerful means for the diffusion of ideas and a useful aid in a propaganda of enlightenment. In a fine play the spectator takes in the lesson without noticing that it is a lesson, and without weariness; and the impressions which he receives are engraved on his mind, not only by what he hears, but what he sees.

BRAIN WEIGHT IN REGARD TO MENTAL CAPACITY.

Brain weight may be said to be a subject of merely academic interest, possessing little or no practical significance. The numerous investigators who have delved into the matter, although not agreed on all points, are more or less agreed that weight of brain does not endow its possessor with superior mental faculties. Dr. Bernard Hollander, in a paper read at a conversazione of the British Ethnological Society, stated that while the average female brain is not only one inch less in circumference than the male brain and about five ounces lighter in weight, these facts do not denote even comparative "light-headedness," because the size of the entire brain

is not a measure of intellectual capacity, but is a measure of capacity of all the energies taken together. The portions in which the difference between the male and female brains is more marked are those that have to do with force, energy and animal passion, all of which women possess in a less degree than men. On the other hand, those portions which are concerned with the manifestations of the feelings and emotions are more strongly developed. In short, the lesser average weight of a woman's brain does not imply that she is inferior in intellect to man. Woman, however, possesses a dissimilar mental capacity to that of man, but whether this be due to the brain or to other causes can not be stated definitely.

That brain weight has little influence on mental capacity, however, has been proved times without number. The old belief that men of real brain power had brains of great weight has been somewhat rudely overthrown of late years.

In the *Journal of the Scientific Society of Saxony*¹ Dr. F. Marchand had an article on brain weights. He weighed 1,334 brains, as a rule, immediately after their removal from the body and while still enclosed in the dura mater. His results were briefly as follows: The mean weight of brain in the male between the ages of 15 and 80 years was 1,400 grams and in the female 1,275 grams. In 84 per cent. of all adult males between the ages of 15 and 80 years the brain weighed between 1,250 and 1,550 grams. About 50 per cent. of the brains examined weighed from 1,300 to 1,450 grams; 30 per cent. weighed over 1,450 grams, and only 20 per cent. weighed under 1,300 grams. As to women's brains, 91 per cent. of all the adults had a brain weight of between 1,100 and 1,450 grams, 35 per cent. weighed 1,200 to 1,350 grams, 20 per cent. over 1,350 grams, and 25 per cent. below 1,200 grams. It was ascertained by the investigator that the brain weight at birth doubled in the course of the first nine months of life and trebled before the expiration of the third year. From this date the increase was much slower in females than in males. The brain of the male reached its definite or ultimate weight at about the nineteenth or twentieth year and in females from the sixteenth to the eighteenth year. The decrease in the mean weight of the brain due to the supervention of senile atrophy occurs in males in the course of the eighth decade, in females in the seventh, though, of course, great individual differences are observable. In adults there is no constant relation between body weight and brain weight, still the mean weight of the brain in males of short stature is somewhat less than in those of average height, and the same holds good for women under the average height. The smaller size of the brain in women, however, is not dependent on the lower stature, for the mean weight of the brain in women is without exception smaller than that of males of equal height.

The above are the conclusions arrived at by an earnest

and scientific student, and in the main, perhaps, are in unison with the views of those who have made a special study of this particular form of research. Objection may be made to the statement that the brains of women are more subject to deterioration from the inroads of age than the brains of men under similar conditions. Dr. Sims,² in an article dealing with brain weight and mental capacity, cited numerous instances in which the brains of celebrated men had been found to be of lesser weight than those of idiots and of ordinary individuals. The brain of Turgenieff, the Russian novelist, was exceptionally heavy, but was considerably exceeded in weight by that of an ignorant and unknown workman. Gambetta possessed an especially light brain, less in weight than that of the average child. Daniel Webster, Napoleon, Byron and Agassiz had brains whose weight did not surpass those of the ordinary man in the street. On the other hand, idiots and imbeciles have frequently extremely heavy brains.

Dr. Sims was of the opinion that, as a rule, larger brains appertain to natives of colder climates.

It would seem, then, that it has been proved, if not with absolute exactitude, at least with sufficient data to support the contention in a satisfactory manner, that heavy brains are no criterion of an individual's intellectual powers, and, further, that the lesser weight of women's brains does not imply mental inferiority in the female sex. It is not the weight of the brain that counts, but the quality, and whence is derived the quality is a moot point.

THE RAY OF LIFE FRAUD.

The downfall of a rank nostrum in New York City has created considerable sensation there because of the large number of persons who were easily duped by the ridiculous claims of the wily exploiters. The Force of Life Chemical Company maintained elaborate offices on Broadway for a number of years, and by alluring advertisements secured the patronage of thousands of people. They loaned "Life Ray Capsules" to patients who signed agreements to take good care of the capsules and to return them to the company. When the post-office authorities, at the instigation of the New York County Medical Society, began to investigate the fraud they doubted the ability of the company to send out so many capsules containing radium because of the cost of this substance, and an investigation showed that the capsules contained only a cheap phosphorescent powder. The business was therefore stopped. The patients had been told by the company: "Hold a capsule near a glass of water for two minutes, drink the water and you have one of the most efficient remedies for nervousness, hysteria, melancholy, dyspepsia and general run-down conditions." Other medical advice given patients was to insulate their beds with glass castors, to use onion poultices, to tie ham rind thickly peppered and wrapped in cheese-cloth over their kidneys, etc. The concern received thousands of samples of blood

from patients, and the postoffice inspector reports that these were destroyed by the colored janitor without examination or analysis, the diagnoses being made by two young women who were drawing \$8.00 a week. The *New York Times*, in commenting on this swindle, says: "Indignation is wasted on the inventors and active workers of the grotesquely obvious swindle. What they did ranks, so far as intelligence and courage go, with stealing doormats or running a policy game." "The real horror of the case lies in the fact that, in this day and land, thousands of men and women can be caught and robbed with no better bait. If one did not know of the fortunes made in similar ways by the exploiters of pseudo-mysticism ranging from voodoo charms down to Eddyite theology, and by the innumerable quacks who live by selling for more dollars than they cost cents the familiar simples that form the quack's only and sufficient stock in trade, it would be possible to be astonished by the long and large success of this silly fraud. But one does know these things, and one can not be astonished at a thing that has been happening every day much longer than anybody can remember. The only possibility is to feel a deep humiliation and fierce disgust that our common schools have done so little for us that a shamefully large minority of the American people are so easily gulled as ever were naked savages, and that no assertion of ability to 'heal' can be so absurd that they will not believe it or pay for its pretended exercise." "The County Medical Society, many as have been its services by hunting down quacks, never did anything better in this line than when it dragged the names of these 'respectable' men into the light of public scorn." The public needs language of this kind straight from the shoulder, but how seldom do they get it! This fraud is gone, but hundreds of others are still in active operation and the public is still ready and anxious to take the bait.

ANESTHESIA VERSUS HOMICIDE BY NEGLECT.

There seems to be a confusion in the minds of some as to the real position of the medical profession regarding the relief of pain in incurable disease. A Catholic bishop recently wrote a letter to an eastern paper deprecating not only the proposition advocated by Professor Norton and others, but, furthermore, denouncing the production of insensibility by anesthetics in severe painful disease and, by inference at least, charging the medical profession with practically anticipating, and perhaps hastening, death by benumbing consciousness and feeling. He is not aware of the fact apparently that excessive pain is itself an exhaustive factor, and a certain degree of analgesia, artificially produced, is often a life-saving measure. Even if it does not save life it prolongs it. Moreover, in incurable disease attended with severe nervous symptoms, painful convulsions, etc., such as tetanus and hydrophobia, it is often the very best treatment, and the physician who hesitates to employ it takes the responsibility of possibly hastening death. There is no spiritual value to unendurable sufferings which themselves engross the attention to the exclusion of all other things for the time being, and such may easily be the case in many disorders. Suffering is not in itself a blessing and does not always serve any

2. Popular Science Monthly, December, 1898.

moral utility. The argument was well answered many years ago at the time of the introduction of anesthesia and it is a little surprising to see it revived now. We do not believe that the bishop himself would justify the withholding by the physician of the remedies that will inhibit the often fatal convulsions of lockjaw or rabies, even if they do benumb or abolish consciousness. Certainly not if he appreciated conditions, nor could he well justify the shortening of human life by their neglect.

A WELCOME CORRECTION.

Mrs. Maud Ballington Booth, who has been quoted with the reprehensible Hall-Norton-Crosier coterie as advocating the painless homicide of assumedly hopeless sufferers, has written to a New York paper denying that she ever expressed the opinion that the incurably sick or injured should be put out of existence. Perhaps the statement was started by some of the advocates of legalizing of homicide, who in their zeal for their cause were not too scrupulous as to the arguments or facts they adduced. The denial is eminently satisfactory, for many were pained by the suggestion that anyone so prominent in good work should be so morally and mentally out of gear as to support the proposition. These morbid dreads of pain will have to go farther and fare worse in their search for sympathizers.

Medical News

CALIFORNIA.

Long Beach Medical Society.—At its annual meeting Dr. Homer O. Bates was elected president of this society; Dr. Joseph M. Holden, secretary, and Dr. W. W. Harriman Jones, councilor.

Sanatorium Sold.—The Loma Linda Sanatorium, which was purchased several years ago by a number of physicians of Los Angeles, has not proved profitable and the hospital has been sold to the Adventists, who will continue the work.

Fire Damage.—By a fire in the Douglass Building, Los Angeles, January 11, Dr. Ralph Williams sustained a loss of \$1,500, and the offices of Drs. David B. Thornton, Charles D. Lockwood and Frank S. Dillingham were seriously damaged by fire, smoke and water.

Measles Epidemic.—The large number of cases of measles and whooping cough in Alameda in December has caused the board of health to take unusual precautions to stamp out these diseases. The classrooms in the schools where measles and whooping cough are most prevalent have been thoroughly fumigated by order of the board of health.

New Health Officers.—Dr. William E. Gibbons has been elected president, and Dr. W. M. S. Behee, vice-president, of the Stockton Board of Health, and Dr. S. Walter R. Langdon, city health officer.—Dr. Maurice W. Brown has been appointed a member of the Alameda Board of Health, vice Dr. William A. Brooke, retired.—Dr. Louis G. Thompson has been appointed a member of the Gridley Board of Health.—Dr. J. S. A. Cabral, Centerville, has been appointed health officer of Alameda County, vice Dr. George F. Chalmers, Niles, deceased.—Dr. C. E. Stone, Marysville, has been re-elected physician of Yuba County.—Drs. Matthew D. Pratt, Fall River Mills; Adelbert B. Gilliland, Cottonwood, and John H. Soot-hill, Anderson, have been appointed special health officers of Shasta County.

Personal. Baron K. Takaki, surgeon general of the Imperial Japanese Navy (retired), arrived in San Francisco from Japan, January 12.—Dr. Garrett Newkirk, Pasadena, has been appointed a member of the State Board of Dental Examiners.—Dr. F. A. Corbys, Visalia, health officer of Visalia and Tulare County, was knocked down by a bicycle December 23, break-

ing his nose and sustaining other injuries.—Dr. William B. Stephens, San Francisco, for five years a surgeon in the Emergency Hospital, has announced that he will resign.—Dr. Frederick C. Gerlach, San José, who has been seriously ill with typhoid fever, is now convalescent.—Dr. and Mrs. Albert Abrams, San Francisco, have started for Europe.—Dr. George A. Hare, Fresno, will be a delegate for California to the International Medical Congress, Lisbon.

Lane Lectures.—The twenty-fourth annual course of Lane lectures was begun January 12 at Cooper Medical College, San Francisco. The following lectures will be delivered:

January 26: Dr. William Ophüls, "The Prevention of Epidemics." February 9: Dr. Adolph Barkan: "The Life and Work of Hermann von Helmholtz."

February 23: Prof. F. M. MacFarland, professor of history, Leland Stanford University, "The Organs of Vision in Lower Animals."

March 9: Dr. William Fitch Cheney, "Some Mysteries of Our Mechanism."

March 23: Dr. W. E. Garrey: "A Pair of Eyes."

April 6: Dr. Thomas W. Huntington, "The Academic Hospital: Its Purpose and Ideals."

April 20: Dr. George B. Somers, "Physiognomy."

May 4: Dr. G. M. W. Lehmann, "Use and Abuse of X-Rays."

May 18: Dr. Albion W. Hewlett, "The History of Some Famous Nostrums."

ILLINOIS.

Hospital Sold.—To satisfy claims of creditors St. Joseph's Hospital, Paris, has been ordered to be sold. The claims against the institution amount to about \$10,000.

Epidemic Disease.—At McLean, the prevalence of diphtheria has resulted in the prohibition of public gatherings and the enforcement of quarantine.—Scarlet fever is reported to be epidemic on the Galena road, north of Peoria.—Spring Valley schools have reopened after several weeks' closure on account of smallpox.

Personal.—Dr. J. Sheldon Clark, Freeport, has been appointed interne in the Illinois Asylum for the Incurable Insane, Bartonville, Chicago.—Dr. Thomas H. Wagner, Joliet, has been appointed a member of the surgical staff of the Rock Island System.—Dr. Jefferson R. Hobart, Ashmore, had a second cerebral hemorrhage, January 1, and is critically ill.—Dr. Lewis D. Dunn, Moline, after a protracted illness, has recovered sufficiently to resume practice.

Objects to Dunning Incurables.—Dr. George A. Zeller, superintendent of the Illinois Asylum for the Incurable Insane, Bartonville, has registered a vigorous protest with the State Board of Charities, claiming that filthy and dangerous patients are being sent there from Cook County in large numbers. Dr. Vaclav A. Podstata, superintendent of the Cook County Institutions, acknowledges that he has sent such patients to Bartonville, but in doing so has followed the provisions of the law. He says that there is no justification for the complaint.

Examination for State Hospital Positions.—The State Civil Service Commission announces that some time in February an examination will be held for assistant physicians in the state hospitals for the insane. This examination will be open to physicians between the ages of 25 and 35, and will include surgery, medicine and nervous and mental diseases. The weights given to subjects will be: Experience, 30, and technical knowledge, 70. For further information address Joseph C. Mason, secretary and chief examiner, room 808, 218 La Salle Street, Chicago.

Chicago.

Increases in Deaths.—For the week ended January 20, 29 more deaths were reported than for the preceding week. Of these cancer showed an increase of 12, convulsions an increase of 4, and nervous diseases an increase of 13.

Mortality of the Week.—During the week ended January 20, 611 deaths were reported, equivalent to an annual death rate of 15.55 per 1,000. Chief among causes of death were: Pneumonia, 111 deaths; consumption, 69; Bright's disease, 43; heart disease, 39; violence, 37, and cancer, 36.

To Protect Children from Tuberculosis.—The Board of Education has adopted a report made by Superintendent Cooley and Dr. E. C. Dudley, providing for a medical examination of pupils supposed to be suffering with tuberculosis and giving the superintendent authority to exclude pupils found to have the disease from the schools.

Contagious Diseases.—Serious increases were noted last week in the contagious diseases. Scarlet fever had 100 cases, 8 more than in the previous week, and 79 more than in the corresponding week of 1905. Of diphtheria 117 cases were reported, 41 more than in the previous week and 68 more than for the corresponding week of last year.

Uphold Health Commissioner's Methods.—The committee appointed by the Chicago Medical Society to make a study of the methods and work of the Department of Health in the nomenclature and classification of death causes and the registration of vital statistics, to report defects discovered and to suggest practical remedies therefor, has reported, indorsing the methods and commending the work of the department.

New Hospitals.—The Chicago Lying-in Hospital and Dispensary intends to build a new hospital to cost \$200,000. Plans are being made for a nurses' dormitory for the Mary Thompson Hospital for Women and Children, to accommodate 31 nurses, and to cost about \$20,000. Plans have been prepared for the Cribside Pavilion to be built in connection with the Chicago Memorial Hospital, to cost about \$40,000.

MARYLAND.

Fees in Last Illnesses.—A bill has been introduced in the legislature giving physicians the same protection in the collection of fees for professional services in the last illnesses as are now afforded undertakers.

Illegal Practice.—Dr. J. G. Sexton was arrested at Cumberland on the charge of practicing without being registered, and was fined \$10 and costs. He appealed and gave bond. The grand jury has returned an indictment against Dr. John A. Watson, Frostburg, on the charge of practicing medicine without registration.

Baltimore.

House Fumigation After Tuberculosis.—Dr. Bosley, health commissioner, announces that he will rigidly enforce the state law requiring the fumigation of houses which have been occupied by consumptives before new tenants move in.

Hospital Report.—The Hebrew Hospital reports 301 patients admitted and 7,269 treated in the dispensary. The total expenses were \$32,246, leaving a small balance on hand. Legacies and memorials amounting to \$4,700 were reported.

Tuberculosis Lecture.—Dr. Charles P. Emerson of the Johns Hopkins Hospital lectured to the Bohemians of the city on tuberculosis, January 19, under the auspices of the Maryland Tuberculosis Association. His remarks were translated by interpreters.

MASSACHUSETTS.

Fines of the Year.—Dr. Charles Harrington, secretary of the State Board of Health, reports that the fines paid amounted to \$8,486 last year, distributed as follows: Milk and milk products, \$1,308; other foods, \$6,390; drugs, \$780. He complains that some district judges are unwilling to impose a fine after the conviction.

Boston's Water Supply.—The report of the metropolitan water board of Boston and vicinity shows that the present reservoirs will contain 82,598,830,000 gallons, and a daily supply from all sources of 173,000,000 gallons. This includes the new Wachusett reservoir, completed December 12, with a capacity of more than 63,000,000,000 gallons. Into this the Nashua brings on the average 111,000,000 gallons daily. Plans are already outlined to go further west and get 71,000,000 gallons a day from the Ware River, and possibly a new reservoir to hold the waters of the Swift River, near Enfield. At present the average daily consumption of water in the district is about 115,000,000 gallons.

Study of Smallpox.—At the meeting of the Boston Society of Medical Science, January 16, Dr. Walter R. Brinkerhoff reported the results obtained by the work which he and Dr. E. E. Tyzzer did last year in Manila in the study of smallpox in monkeys. Confirmation of the organism discovered by Dr. Councilman was obtained, the two cycles being distinctly traced. True smallpox could not be obtained in monkeys, however, save by inoculation, when a mild form like varioloid was produced. Successful inoculations from the pustules to a fresh monkey and so on showed the two cycles still preserved, but the power of the virus gradually faded out. Vaccinia, on the other hand, with its single cycle, was as readily produced in monkeys as in man.

MICHIGAN.

New Secretary and Editor.—At the meeting of the council of the Michigan State Medical Society, held in Detroit, January 12, Dr. Andrew P. Biddle refused a re-election and Dr. Benjamin R. Schenck was chosen secretary of the society and editor of the state journal.

Immunity.—Dr. Ludvig Hektoen of Chicago, on invitation of the Wayne County Medical Society, delivered an address on "Immunity in Theory, Practice and Experiment," in Detroit, January 15. The lecture was supplemented by a stereo-

option demonstration illustrating some of the author's original researches in immunity.

December Mortality.—The total number of deaths for December was 2,683, representing an annual death rate of 12.4 per 1,000 population, as compared with a rate of 12.6 for the preceding month. There were 435 deaths of infants under 1 year of age, 16 deaths of children aged 1 to 4 years inclusive, and 896 deaths of persons aged 65 years and over. Important causes of death were as follows: Tuberculosis, 210; typhoid fever, 51, a marked decrease from the preceding month, which had 93 deaths; diphtheria, 66; scarlet fever, 18; measles, 10; whooping cough, 16; pneumonia, 228, as compared with 187 for the preceding month; diarrheal diseases of infants under 2 years, 36; influenza, 23; cancer, 123, and violence, including accidents, 167. No deaths from smallpox were reported during the month.

State Board Doings.—At the meeting January 12, on suggestion of the secretary, it was decided by the board that hereafter the title of the official organ of the department should be "Public Health, Michigan." All pamphlets and bulletins issued by the department, including the teachers' sanitary bulletins, will be issued under this head, and will be bound in attractive covers and in suitable form to insure preservation. This method has been adopted by reason of the substantial saving in postage that will result, it being estimated that the postage of the department will be reduced fully one-half thereby. The board decided to co-operate with Prof. Delos Fall of Albion College, a former member of the board, in an endeavor to ascertain from the analysis of the uncontaminated spring waters of the state a definite chlorine standard for a pure water, a sum of money being set aside out of the appropriation to defray expense of carrying on this investigation. A committee of the board on public water supplies was appointed, comprising Drs. Vaughan, Sinclair and Shumway, to co-operate with a similar committee from the State Engineering Society and State Medical Society, in an endeavor to secure legislation to invest a commission with power to investigate and advise regarding public water supplies.

NEW YORK.

Erie County Society Election.—At the eighty-fifth annual meeting of the Medical Society of the County of Erie, held in Buffalo, January 9, the following officers were elected: Dr. Albert H. Briggs, president; Dr. Edward Clark, vice-president; Dr. Franklin C. Gram, secretary; Dr. DeWitt C. Greene, treasurer; censors, Drs. Henry R. Hopkins, DeLancey Rochester, Irving W. Potter, John H. Grant, and Francis E. Fronczak; committee on legislation, Drs. Arthur G. Bennett, William C. Krauss and Ernest Wende, and committee on membership, Drs. William Warren Potter, Charles A. Walls and Albert T. Lytle, all of Buffalo.

Centennials of Societies.—The centennial meeting of the Medical Society of the State of New York, to be held in Albany, January 30 and 31, and February 1, will be of unusual interest, as it is the first meeting of the united profession of the state secured in the judicial order of the Supreme Court, December 9, consolidating the two state medical bodies which have existed separately for many years. A history of the first hundred years of the society is being presented. Public addresses will be delivered by Hon. Grover Cleveland, Hon. St. Clair McKelway, the governor of the state, the mayor of Albany, and the president of the society, Dr. Joseph D. Bryant, New York City. Montgomery County Medical Society celebrated its centennial at its meeting, January 10, at Fonda, where it was entertained by Dr. Frederic I. Jansen. The centennial of Dutchess County Medical Society was celebrated at Poughkeepsie, January 10. The following officers were elected: Dr. John H. Cotter, Poughkeepsie, president; Dr. D. H. McKenzie, Millbrook, vice-president; Dr. Robert W. Andrews, Poughkeepsie, secretary, and Dr. David B. Ward, Poughkeepsie, treasurer. Dr. Guy C. Bayley, superintendent of Vassar Brothers' Hospital, Poughkeepsie, gave a historical address, in the course of which he read the minutes of the first meeting, held Sept. 20, 1806, and gave brief biographic sketches of past presidents. Dr. Joseph D. Bryant, president of the Medical Society of the State of New York, spoke of the causes which led to separation 24 years ago, and to the amalgamation just consummated. The anniversary banquet was attended by more than 100 guests. Dr. Henry L. Cockingham, Red Hook, presided as toastmaster.

New York City.

Ship's Hospital on Deck.—The new twin screw steamship *Brazil*, of the Veloce Line, has a pharmacy, operating room and hospital on the upper deck.

Increase in City's Death Rate.—The death rate for the week ended January 13 was equivalent to 19.16 per 1,000, as against 18.77 a year ago. The increase is due to an unusual number of cases of pneumonia, diphtheria and measles.

Sixth Harvey Lecture.—The sixth lecture in the Harvey Society course will be given by Prof. Lewellys F. Barker of Johns Hopkins University, at the New York Academy of Medicine, Jan. 27, 1906, at 8:30 p. m. Subject, "The Neurones."

Croton Dam Completed.—After thirteen years of work and an expenditure of \$8,000,000, the Croton dam has been finished, thereby supplying a new reservoir which is nineteen miles long by two and a half wide, with a capacity of 300,000,000 gallons.

Another Ambulance Collision.—An ambulance belonging to the Lincoln Hospital, while conveying a patient to Harlem Hospital, collided with an express wagon on the Willis Avenue bridge, January 17. The ambulance surgeon and a policeman were thrown out and badly bruised.

Tuberculosis Exhibit Opened.—Health Commissioner Darling-ton opened the tuberculosis exhibit, at Second Avenue and Thirtieth Street, January 16. Physicians on the East Side are aiding in this method of educating the people with regard to tuberculosis. The exhibit will continue until January 27.

Communicable Diseases.—There were reported to the Sanitary Bureau for the week ended January 13, 1,214 cases of measles, with 15 deaths; 397 cases of tuberculosis, with 173 deaths; 222 cases of scarlet fever, with 7 deaths; 32 cases of typhoid fever, with 6 deaths; 23 cases of cerebrospinal meningitis, with 26 deaths; 2 cases of smallpox, and 205 cases of varicella.

Health Department Boat Launched.—Mayor McClellan and the Health Department officials were present at the launching of the *Riverside*. This boat was built for the use of the Health Department at a cost of \$67,000; it has four decks and eight separate wards, so isolated that patients suffering from contagious diseases may be carried to the island hospitals without danger to other patients.

Hospital News.—Plans have been filed for the making over of two four-story tenement houses, recently acquired by the French Benevolent Society, into an annex for the new hospital, at a cost of \$17,000.—The number of patients treated from Oct. 1, 1904, to Oct. 1, 1905, in the New York Infirmary for Women and Children was 1,005; in the dispensary, 8,968, and in the outpatient department, 1,194.—At the annual meeting of the directors of Mount Sinai Hospital it was reported that 5,330 patients had been admitted to the hospital during 1905, as against 3,876 in the preceding year. In the dispensary 53,771 patients were treated, 154 in the outdoor department and 1,086 in the accident ward.

The City Milk Supply.—In a report issued by the Department of Agriculture on the milk supply of Philadelphia, Boston and New York, it is pointed out that the task of safeguarding the supply of this city is a particularly difficult task, as the milk comes from over 200,000 cows, distributed among 9,000 dairy farms, some of them 200 miles from the city. In addition the conditions relating to transportation must be regulated. Out of a total of 2,458 stores visited only 154 were found where the milk was properly cooled and where there was no communication with living rooms. In the Court of Special Sessions, after a long calendar of cases had been brought in by the Health Department, eight doctors were convicted and fines amounting to \$205 in the aggregate were imposed. The judge stated that hereafter anyone who was convicted a second time for selling adulterated milk would be imprisoned, and that the sentence would be heavy. Commissioner Hebbard of the Department of Charities warmly indorses the newspaper crusade for pasteurized milk. He thinks that the milk used in the hospitals and city institutions should be pasteurized, and would have asked for an appropriation for this purpose had not the funds been apportioned before he came into office.

NEW JERSEY.

Society Officers Elected. At the annual meeting of the Burlington County Medical Society, held in Burlington, January 10, the following officers were elected: President, Dr. Joseph Stokes, Moorestown; vice-president, Dr. J. Edward Blair, Burlington; secretary, Dr. George T. Tracy, Beverly; treasurer, Dr. Enoch Hollingshead, Pemberton. The annual meeting of the Atlantic County Medical Society was held January 12. The following officers were elected for the ensuing year: President, Dr. Elisha C. Chew; vice-president, Dr. Edwin H. Har-

vey; secretary-treasurer, Dr. Edward Guion, and reporter, Dr. Burton Shimer; nominee for permanent delegate to the Medical Society of the State of New Jersey, Dr. Emory Marvel, and annual delegates to the Medical Society of the State of New Jersey, Drs. David Berner and George Scott, all of Atlantic City.

Condemn Non-Medical Health Officers.—At meetings of the Atlantic City Academy of Medicine and the Atlantic County Medical Society, January 12, the following resolutions were adopted:

Resolved, The Board of Health of Atlantic City, at its regular meeting, Jan. 11, 1906, under political pressure abolished the position of health officer, and decided to return to the old system of inspection by non-medical men. Be it

Resolved, That in the abolition of this office the board of health is taking a step backward and will reduce its efficiency in protecting the health of citizens and visitors.

Resolved, That the board of health be requested to reconsider its present action and appoint some fully qualified medical health officer who will do his duty, irrespective of political or other influence.

Resolved, That the Atlantic City Academy of Medicine condemn the action of the board of health in making the board of health a political body.

Resolved, That a copy of these resolutions be mailed to the secretary of the Board of Health of Atlantic City, N. J., and to the secretary of the New Jersey State Board of Health; also to THE JOURNAL of the American Medical Association and the Journal of the Medical Society of New Jersey.

NORTH CAROLINA.

Personal.—Dr. James D. Heathman, Woodleaf, broke his arm December 28 while wrestling.—Dr. S. N. Glenn, Gastonia, has been elected physician of Gaston County, vice Dr. Henry F. Glenn, resigned.

Smallpox.—Hope Mills has an epidemic of smallpox. It is reported that there are 200 cases, but that none is serious. The health authorities of Raeford and Lafayette are taking rigid action to prevent a spread of the disease.

Mecklenburg County Medical Society.—At the annual meeting of this society December 5 the following officers were elected: Dr. W. W. Pharr, Newell, president; Dr. Walton O. Nisbet, Charlotte, vice-president; Dr. Parks McC. King, Charlotte, secretary and treasurer; Drs. John R. Irwin and Thomas F. Costner, Lincolnton, censors; Drs. Isaac W. Faison and Robert E. Mason, Charlotte, delegates to the state medical society, and Drs. Charles A. Meisenheimer, Charlotte, and Simmie M. Henderson, Croft, alternates.

OHIO.

Hospital in Trouble.—Suit has been begun in Marion to have a receiver appointed for the Marion City and County Hospital Company, which has liabilities estimated at \$15,000.

Fire at State Hospital.—Fire which started in the carpenter shop at the State Hospital for the Insane, Columbus, January 8, caused \$2,500 damage to the building and \$3,000 or more to the contents. None of the patients was injured.

Fraud Order Issued.—The postoffice department has issued a fraud order against the Western Remedy Company, Cincinnati, as the result of an investigation by Inspector Swanson as to its methods in selling a preparation claiming to cure all ills.

Personal.—Dr. Zachariah T. Housman, Fostoria, has been ill for ten days with lithemia and autotoxemia.—Dr. W. A. Gowing, Toledo, is convalescent after a serious attack of tonsillitis.—Dr. Elmer W. Heltman, Toledo, is seriously ill with tuberculosis.

Academy Election.—The Academy of Medicine of Dayton elected the following officers at its annual meeting, January 12: President, Dr. Edwin M. Huston; vice-president, Dr. A. L. Light; treasurer, Dr. Harry E. Patten; secretary, Dr. A. W. Bartle; censors, Drs. Clifton L. Patterson, W. A. Ewing and William C. Marshall, and program committee, Drs. A. H. Dunham, Richard S. Gaugler and H. B. Harris.

Personal.—Dr. Benjamin L. Milliken, Cleveland, has gone to Jamaica for a month.—Dr. Charles S. Means, Columbus, has been elected president of the board of education of that city.

—Dr. Louis R. Culbertson, Zanesville, sailed from New York for Europe January 7.—Dr. Duncan D. McCallum, Crestline, fell and strained his back December 31.—Dr. William D. Hamilton, Columbus, who was operated on in Chicago for appendicitis two months ago, has returned home.—Dr. George W. Burnett, Greenville, has been appointed health officer.

Councilor District Meeting.—The meeting of the Fifth Councilor District Medical Society of Ohio at Marietta, January 11, was attended by 65 physicians and the work done was of great interest. Dr. E. C. Brush delivered an eloquent ad-

dress entitled, "Are We Garnering Sheaves by Organization?" in which he gave the history of the state and national organizations and stated his belief that the future power of the American Medical Association would force the proper recognition of the medical profession by the passage of laws protecting the profession, and the acknowledgment of the rightful demand that a public health officer should be a cabinet officer. The society was entertained by the Washington County Medical Association. At the close of the program Dr. Stephen A. Cunningham, Marietta, was elected president, and Dr. Charles H. Jiggins, Zanesville, secretary and treasurer.

PENNSYLVANIA.

County Society Officers.—At the regular meeting of the Philadelphia County Medical Society, January 17, the following officers were elected: President, Dr. Charles K. Mills; vice-presidents, Drs. James B. Walker, Aloysius O. J. Kelly, Levi J. Hammond, A. Bern Hirsch, Charles A. E. Codman, and James C. Chestnut; secretary, Dr. William S. Wray; assistant secretary, Dr. Ross H. Skillern; treasurer, Dr. Collier L. Bower, and censor, Dr. Frederick P. Henry. Dr. Albert M. Eaton was recommended to the Medical Society of the State of Pennsylvania for district censor.

New Rules for Burials.—Owing to the fact that cemetery sites have been selected without regard to the geologic formation, and that many are not suited for the purpose of properly protecting the health of the persons in their respective localities, the State Department of Health has decided to adopt the following rules and regulations: "Except by special permission from the Department of Health no interment of any human body shall be made in any public or private burial ground unless the distance from the top of the box containing the coffin or casket be at least five feet from the natural surface of the ground, except where solid rock or water may be encountered. Then the distance from the top of the box containing the coffin or casket shall be not less than four feet from the natural surface of the ground, and with the further exception that stillborn children and children less than 4 years of age dead of any diseases other than anthrax, cholera, diphtheria, leprosy, smallpox, scarlet fever, tetanus, typhoid fever, typhus fever or yellow fever, shall be buried at such a depth that the top of the box containing the coffin or casket be not less than three and one-half feet from the natural surface of the ground."

Philadelphia.

Personal.—Dr. Robert S. Engler is seriously ill with typhoid fever. Dr. Raymond A. Dinan, who mysteriously disappeared from his home in this city, was found in Atlantic City, ill with typhoid fever.

Report of Hospital.—The report of the Polyclinic Hospital for 1905 shows that 1,320 patients were treated in the wards, and that 100,923 visits were paid to the various dispensaries. The treasurer's report shows a deficit for the year of \$10,727.22.

W. B. Saunders Company.—The business of the late W. B. Saunders has been incorporated under the name of W. B. Saunders Company, with a capital of \$400,000. The officers are: F. B. Saunders, president; W. B. Watson and R. W. Greene, vice-presidents, and E. V. Hall, secretary and treasurer. This means that the business will be conducted as before Mr. Saunders' death.

Dr. Takaki Here.—Baron Kanehiro Takaki, ex-surgeon general of the imperial Japanese navy, was a guest at the University of Pennsylvania, January 19. He was entertained by Dr. Charles Frazier, dean of the medical school. Dr. Takaki is by special permission of the emperor delivering a course of lectures at Columbia University, and in about two weeks he will begin a series of lectures at Jefferson Medical College. While in the city he was the special guest of Provost C. C. Harrison of the university, and Mr. William Parker.

Medical Club Banquet.—The annual meeting and banquet of the Philadelphia Medical Club was held in the Majestic, January 19. The following officers were elected: President, Dr. Roland G. Curtin; vice-presidents, Drs. Wharton Sinkler and Henry Beates; governor, Dr. G. G. Davis; treasurer, Dr. Lewis H. Adler, Jr.; secretary, Dr. J. Gurney Taylor, and executive committee, Drs. H. H. Whitcomb, Norristown, Pa.; Emory Marvel, Atlantic City, and Wilmer Krusen, Edward E. Montgomery and Ernest Laplace, of Philadelphia.

Bequests.—By the will of the late Moses Geisenberger of Lancaster, the Jewish Asylum, Jewish Hospital, and the Jewish Foster Home each receive \$500. The will of the late Dr. Thomas C. Potter bequeaths to the University of Pennsylvania his medical library, and also the sum of \$10,000 to the

university "to build or establish or endow a dormitory to be known as the John C. Potter dormitory."—By the will of the late Francis W. Lang, St. Timothy's Hospital and House of Mercy will receive \$5,000 for the endowment of a bed to be known as the John Lang Memorial.

Medical Inspection of Schools.—The report of the chief of the Bureau of Health on medical inspection for the year 1905 shows that 43 children found to have diphtheria, and 59 additional children who had been in contact with diphtheria cases; 118 cases of measles and 58 children who had been in contact with cases of measles; 173 children who were suffering from chicken-pox; 87 from whooping cough; 37 from scarlet fever, and 19 children who had been in contact with scarlet fever cases were excluded from schools. The figures for diphtheria show 300 less cases last year than in 1904.

Health Report.—The total number of deaths reported for the week ended January 20 reached 633, as compared with 582 reported last week, and 519 the corresponding week of last year. The principal causes of death were: Typhoid fever, 16; measles, 28; whooping cough, 6; diphtheria, 21; consumption, 75; cancer, 31; diabetes, 6; apoplexy, 16; heart disease, 55; acute respiratory disease, 104; enteritis, 23; Bright's disease, 36; premature birth, 14; suicide, 4; accidents, 19, and marasmus, 12. There were 373 cases of contagious disease reported, with 37 deaths, as compared with 421 cases and 40 deaths for the preceding week. There were 240 new cases of typhoid fever reported, with 16 deaths, while in the preceding week there were 267 cases reported, with 23 deaths.

Statue for Dr. Leidy.—A circular has been issued by a number of citizens asking for contributions toward a fund to erect a statue of Dr. Joseph Leidy on the plaza of the City Hall in recognition of his memorable work in the field of natural science. The circular says that as the president of the Academy of Natural Sciences, professor of human and comparative anatomy and zoology in the University of Pennsylvania, and president of the Wagner Free Institute of Science, Dr. Leidy added immeasurably to the position these institutions already held in the world of science. His reputation was international. It dignifies the city to which his fame belongs. Philadelphia, the place of his birth and death (1823-1891), and the scene of his labors for a half-century, has thus far failed to show any practical appreciation of his varied labors in the field of original research. It is proposed to erect a statue for \$10,000. The physicians of this city who have signed the circular are: Drs. H. C. Chapman, S. G. Dixon, F. X. Dercum, Horace Jayne, R. H. Harte, George E. de Schweinitz, Thomas Biddle, Joseph Leidy, Jr., Joseph P. Tunis, William Osler, John H. Musser, Arthur V. Meigs, R. G. LeConte, W. C. Posey and J. H. Adams.

WEST VIRGINIA.

Cabell County Society.—The medical society of this county held its annual meeting December 14, at which the following officers were elected: President, Dr. Archibald Cray, Huntington; vice-president, Dr. Wesley D. Hicks, Central City; treasurer, Dr. Isaac R. LeSage, Huntington, and secretary, Dr. Thomas W. Moore, Huntington.

Mandamus Denied.—In the case of the Monongalia County Court, which brought suit against the West Virginia Board of Health citing it to show cause why it refused to confirm the appointment of Dr. James W. Hartigan, Morgantown, as county health officer, the Circuit Court denied a writ of mandamus, and on January 11 the Supreme Court affirmed the decision of the lower court.

Personal.—Dr. Wesley H. Sharp, Parkersburg, is convalescing after a surgical operation. Dr. and Mrs. Gustavus A. Ashman, Wheeling, leave for the Mediterranean next month. Dr. S. Marion Steele, Moundsville, has succeeded Dr. Albert H. Kunst as superintendent of the West Virginia Hospital for the Insane, Weston. Dr. John W. Hyer, Richwood, has been appointed assistant superintendent of the institution. Dr. J. R. Bloss, Huntington, has been appointed assistant physician at the West Virginia Asylum, Huntington.

GENERAL.

Quarantine on Honolulu Raised.—Honolulu has not had a case of plague for sixty days and Dr. Cofer of the Public Health and Marine-Hospital Service has declared the outgoing quarantine removed.

Joint Medical Board.—It is reported from Washington that the President has appointed a joint board of officers of the medical departments of the Army and the Navy to consider improvements in the matter of first-aid dressings and the advisability of the adoption of a uniform equipment in the medical departments of the two branches.

Health Officer for Honduras.—Dr. Wyman, surgeon general of the Public Health and Marine Hospital Service, has assigned Dr. Thomas F. Richardson to Honduras, to be health officer on pay by that country.

Medical Society of the Missouri Valley.—The eighteenth semi-annual meeting of this society will be held at St. Joseph March 22 and 23. The oration on medicine will be given by Dr. N. S. Davis, Chicago, and the oration on surgery by Dr. L. M. McArthur, Chicago. The local arrangements are in the hands of Drs. Jacob Geiger, C. R. Woodson and O. B. Campbell. The secretary of the society is Dr. Charles Wood Fassett, St. Joseph, Mo.

Sanitation in Havana.—According to cable reports the president of the Cuban republic has ordered the enforcement of sanitary ordinances. The decree defines offenses against the sanitary laws and under it the department can inflict penalties for refusal or failure to improve insanitary conditions once notification has been given. Hitherto the department has been hampered owing to lack of authority to enforce the directions of the sanitary officers.

Warning.—We are in receipt of a communication from a physician in California, stating that one giving his name as H. Fred Mace is calling on physicians soliciting subscriptions for THE JOURNAL in connection with a lay magazine, at a great reduction of rates, and is collecting subscriptions in advance. This offer is fraudulent and the money received is presumably retained by the alleged agent. We would again warn physicians to pay no money to agents on account of THE JOURNAL of the American Medical Association, unless the representative has a letter authorizing him to make collections at that time.

Third Congress of French-Speaking Physicians of America.—The two preceding annual congresses were held at Montreal and at Quebec. The third is to convene at Trois-Rivières during the last week of June, 1906. An urgent appeal is being made to all French-speaking medical men and women to co-operate in making this approaching congress a success. The subjects to be discussed will be eminently practical ones. Dr. L. P. Normand and Dr. C. DeBlois of Trois-Rivières are the president and secretary of the congress, supported by an able committee of organization. The congress in the following year will be held on this side of the border.

Gibbs Memorial Prize.—For the best essay on the "Etiology, Pathology and Treatment of the Diseases of the Kidneys" the trustees of the New York Academy of Medicine announce a prize of \$2,000. Essays may be sent Oct. 1, 1907, or before, to Dr. A. Jacobi, chairman of the board of trustees, 17 West Forty-third street. The prize committee does not expect the "etiology, pathology and treatment" of the diseases of the kidneys to be discussed with equal completeness, but will be satisfied with the thorough scientific consideration of part of the problem, provided an essay offered in competition contains new facts or discoveries or points of view of sufficient merit.

Inspection Tour.—It is reported that the United States Fruit Company has placed one of its vessels at the disposal of the health authorities of New Orleans and Mobile in order that they may inspect the Central American fruit ports. The company is desirous of demonstrating its facilities for taking care of infectious diseases, the manner in which the vessels of its line loaded cargo and the position of the anchorage and wharves at the various loading ports. Another object of the proposed trip is to have a conference with the local health authorities at the Central American ports and to secure their co-operation, with a view to establishing safer and better quarantine regulations with New Orleans and Mobile.

Health Report of the Isthmus for November.—The report states that during November Colon underwent the same systematic cleaning to which it has been subjected for several months past. In Cristobal considerable pipe drainage and road building was added to the general work of sanitation. On November 11 Mount Hope cemetery was formally turned over to the health officer and now all burials are under the supervision of that official. The funeral trains are under the charge of a foreman in the employ of the health office, and he is empowered to arrest persons obtruding themselves on the occasion of a funeral. The arrest of two individuals has warned the public that the practice of using funeral trains for excursion purposes is to be stopped. The report also states that much less trouble than formerly is being encountered in the daily administration of quinine to laborers. The majority of cases of malaria have occurred among the more recently arrived laborers from Martinique.

CANADA.

Contract Practice.—The medical men of Regina, Sask., as a body have declared against entering into any contracts with friendly and benefit societies in the future.

Communicable Diseases in Vancouver.—According to Dr. Underhill, the health officer of Vancouver, B.C., there were in that city in 1905, 188 cases of mumps, 26 of diphtheria, 26 of measles, 99 of whooping cough, 7 of tuberculosis, 52 of typhoid fever, 52 of scarlet fever, and 76 of chicken-pox. The death rate for the year, taking the population at 42,000, was 10,571 the total number for the year being 444.

Montreal's Annual Health Report.—Cases of contagious diseases in Montreal during 1905 numbered 2,615, divided as follows: Diphtheria, 529; scarlet fever, 223; typhoid, 392; measles, 929; roseola, 5; variella, 33; whooping cough, 94; tuberculosis, 405; trachoma, 4; cerebrospinal meningitis, 3; corysela, 2.

Personal.—Dr. E. C. Burson, of the house staff of the Toronto General Hospital, has been appointed chief of the interne staff. Dr. Frank Irvin, Souris, Man., has been appointed assistant medical superintendent of the Brandon Provincial Hospital for the Insane. Dr. Norquay of that institution has been transferred to the Selkirk (Man.) institution.

School Hygiene for London.—London, Ont., sent a large deputation to Toronto on January 18 to interview the government with regard to establishing a school for hygiene in that city. Premier Whitney in reply stated that his government would always be prepared to consider any reasonable proposition with regard to medical education in the province of Ontario. A detailed statement of the proposed institution will be placed before the government.

Analysis of "Patent Medicines."—As the Canadian law does not at the present time provide for the department of inland revenue, under which all chemical analyses are made, making any chemical analysis of any of the patent medicines on the Canadian market, pressure is being brought to bear on the dominion government to remedy the existing conditions. At an early date, however, it is understood that the dominion analyst will publish the results of an analysis of several of the best known patent medicines.

Hospital News.—A citizens' committee has been organized in Toronto to collect subscriptions for the Toronto General Hospital. Several influential business firms have subscribed from \$500 to \$1,000 each to this purpose. The total subscriptions to the Toronto General Hospital amounted to \$1,074,541, to January 20. The Western Hospital, Montreal, treated 524 patients during 1905. In the outdoor departments the consultations numbered 6,698. A new wing will be erected to provide for an additional 100 patients. Dr. Grace Ritchie England has resigned from the position of assistant gynecologist to this hospital, a position she held for thirteen years. The resignation of Dr. A. Macphail as pathologist was also received and accepted. During December, 1905, 57 male and 11 female patients were admitted to the Vancouver General Hospital. Six patients died in the institution during that month. During the week ending January 13, 220 men, 111 women and 50 children were treated in the Winnipeg General Hospital. The sixteenth annual meeting of the life governors of the Brandon (Man.) General Hospital was held January 15. This hospital now has accommodation for 120 patients. One citizen of Victoria, B. C., has offered to head a subscription with \$5,000 if the citizens will raise \$25,000 for converting the present Royal Columbia Hospital of that city into an up-to-date and modern hospital. The Ontario Government Institution for Epileptics has been completed at Woodstock. It has accommodation for 70 patients and will have for superintendent Dr. J. J. Williams of Lisle, Ont. On January 12 325 patients, 195 males and 130 females, were in the Toronto General Hospital, the largest number ever in the hospital on a given day. The Ontario government will shortly consider the question of removing the Toronto Provincial Hospital for the Insane to a point outside the city limits. At the Montreal General Hospital during 1905, 3,210 patients were admitted to the wards and 44,377 consultations were held in the outdoor departments. The average daily sick in residence was 204. The Royal Victoria Hospital, Montreal, treated 3,093 patients during 1905. Of the 182 deaths in the institution 57 took place within 48 hours of admission. Dr. J. W. Stirling was appointed ophthalmologist to the hospital to succeed the late Dr. Frank Buller. The Home for Incurables, Toronto, had 132 patients during 1905. There were 4 deaths during December and 8 applications for admission. The following have been appointed to the house staff of the To-

ronto General Hospital, to serve for the usual six months' term. In surgery.—Dr. T. D. Archer, Campbellford, Ont.; Dr. J. H. Soady, Toronto; Dr. J. H. Kidd, Peterboro. In medicine.—Dr. K. H. Van Norman, Toronto; Dr. F. W. Rolph, Markham, Ont.; Dr. F. J. Buller, Toronto.—In 1905 the Winnipeg General Hospital treated 4,366 patients in its wards and in the outdoor departments 5,735. The deaths during the year numbered 332. To show how the work at this hospital has increased during the past five years the following figures are given: In 1901 the in-patients were 2,773; 1902, 2,928; 1903, 3,354; 1904, 3,868. In the outdoor departments the increase has also been great. In 1901 the number was 1,607; 1902, 1,363; 1903, 3,483; 1904, 4,772. The total number of patients treated in the Winnipeg General Hospital during the week ending Jan. 6, 1906, was 357, of whom 222 were men, 86 women and 49 children.—The trustees of the Toronto Free Hospital for Consumptives held their first annual meeting in Toronto, January 13. Dr. Allan Adams, the physician in charge of the institution, presented his first annual report for the hospital year ending September 30. During the year 136 patients in advanced stages of the disease were treated, and over 5,000 people registered as visitors, showing that the community is taking a deep interest in the institution.—Representatives of the various interests in the new Toronto General Hospital met at the Ontario parliament buildings on the afternoon of January 9 and decided that a new board of trustees with 25 members be established, as follows: The Ontario government, 8; the University of Toronto, 5; the city of Toronto, 5; the benefactors, 7. Any one can become a benefactor who up to the time of passing the necessary act to incorporate the institution has donated \$500, and after the act has come into force, \$1,000. The privilege of students visiting the wards shall be confined to the students of Toronto University.—Mayor Urquhart of Toronto, on leaving office, inaugurated a fund for the benefit of the Toronto General Hospital to which he invites 999 other citizens to contribute \$100 each.

FOREIGN.

The Pope and the Miracles at Lourdes.—Dr. Boissarie of Lourdes, France, sent recently, as usual, his annual report to the Pope of the miraculous cures effected at the famous grotto of Lourdes in his charge. He received, in reply, a letter from Dr. Laponi, the medical attendant of the Pope, stating that in future the latter wished to have arrangements made to establish the identity of the persons thus cured, with depositions of physicians and witnesses who had seen the patients before their cure, placing the Lourdes experiences on a more scientific basis than hitherto.

Medical Legislation in Victoria.—It is reported that a bill about to be presented to the government of Victoria, Australia, is to the effect that no degrees will be recognized from universities other than the United Kingdom or a British possession, unless it appears to the medical board that such institutions recognize the medical graduates of the University of Melbourne, and that Melbourne graduates are permitted to register in the country of the university. A clause is introduced prohibiting any persons but registered medical practitioners (and chemists) from dispensing medicine or rendering to any person medical or surgical aid for fee. The penalty for evading these provisions is fixed at \$250.

Plague in Japan.—Passed Assistant Surgeon Moore reports from Yokohama that the strenuous measures enforced at Kobe and Osaka with a view to controlling plague have not as yet proved successful. The present outbreak is the most extensive and alarming one that has yet visited Japan, excluding Formosa. In view of the fact that Kobe ranks with Yokohama as a leading port of the empire and that Osaka is its chief industrial center and second city in point of population, the situation is grave. Chefoo, Chemulpo and Shanghai have all declared quarantine against Kobe. Dr. Kitasato, who is now spending his time between Osaka and Kobe, is of the opinion that plague was imported into Japan by a shipment of Bombay cotton, which was supplied to the cotton mill where the disease started.

Charlatans Imprisoned and Fined in Germany.—One month's imprisonment and a fine of 1,000 marks, about \$250, were imposed recently on a charlatan named Overmann by the court at Haagen. He had advertised that he could cure lupus, cancer, epilepsy, goiter, etc., and fifty witnesses testified that he had cured them of these or similarly serious affections. The suit was brought by the Haagen Medical Society, and testimony was presented showing that Overmann was incapable of diagnosing most of the affections in question. The

penalty imposed was higher on account of the fact that he had been previously sentenced by the courts for similar irregular practices. Kirchberg urges medical societies elsewhere to follow this example of the Haagen association. Systematic arraignment of quacks in this way, he thinks, would do much good. The court at Ulm has also sentenced a quack to seven months' imprisonment for advertising a "sure cure for tuber culosis."

Neisser's Research on Monkeys in the East Indies.—The *Deutsche med. Wochts.* is publishing Neisser's report of his months of research in the Dutch East Indies. He had the largest number of monkeys at his disposal that have ever been collected for a single purpose, a total of about 900, including 11 orang outangs, from 20 to 30 gibbons, and the rest smaller monkeys. He was particularly impressed with the morbidity of the monkeys, intestinal diseases, dysentery and helminths making constant ravages among them. He found that there is not so great a difference between the smaller monkeys and the orang outangs and gibbons in respect to infection with syphilis as has been previously assumed. The higher species are more susceptible, but the infection proceeds about the same in each kind of monkey. All his attempts to preserve syphilitic material for use at a later date proved fruitless. All virulence had vanished by the sixth or seventh hour after removal from the body. Even from the cadaver, inoculations were always negative after an interval of eighteen hours. Excision of the focus a few hours after infection was unable to arrest the generalization of syphilis, and the most varied attempts to prevent the development of the infection after inoculation never proved successful. The generalization of the infection could usually be demonstrated by the fifty-fourth to the hundred and fortieth day after the inoculation. Simultaneous mercurial treatment never succeeded in preventing the development of the primary lesion, and, in one instance, material from a mercury-treated animal proved exceptionally virulent when inoculated into others.

Coroners and Doctors in London.—A dispute has long been pending between the coroner for Westminster and South West London and the medical profession in regard to the employment of the pathologist to the London county council to make autopsies. The custom in London has always been for a local man to do this work, generally the physician who was first called in or the regular medical attendant. The coroner for Westminster ignored this custom, however, and brought into his district the London county council pathologist for the purpose of making postmortem examinations and of attending at inquests to give evidence. Naturally, this aroused the members of the medical profession who, if this method were universally followed, would be deprived of a somewhat valuable source of income, the fee for such work being £2.2 (£10.50). The British Medical Association took up the matter, and, as ratepayers, requested the auditor to disallow certain fees paid by the London county council to the coroner for Westminster, to reimburse him for payments made to the London county council pathologist. The contention of the association was that local medical men were entitled to do the work, and that some hundreds of physicians were affected by the coroner's action. The British coroners' act of 1887 provides that, in the event of the death of a person who has not been seen during life or immediately after death by a duly qualified medical practitioner, "the coroner may call in a medical man in actual practice in or near the place where the death occurred to make a postmortem examination and to give evidence at the inquest." The British Medical Association asserted, at the inquiry, that the London county council pathologist did not practice in or near the Westminster and South London district. The auditor of the Local Government Board came to the conclusion that he is bound to allow the whole of the payments in question, but added that he wished to express his sympathy with those members of the medical profession who had been affected by the coroner's general mode of procedure. The British Medical Association may appeal from this decision, in which case the matter will come before the Local Government Board.

LONDON LETTER.

The Health of the Navy.

A blue-book has just been issued on the health of the navy in 1904, which was very satisfactory. With a personnel increased by 7,470 as compared with the previous year there are decreases in the number of cases, invaliding, and deaths as compared with the average of the last seven years. Contrasted with 1903 the case and invaliding ratios show reductions. The invaliding ratio, viz. 22.7 per 1,000, shows a decrease of 7.28 as compared with the average of the last seven years.

The death rate was 4.45, a decrease of 1.91. The death rate from disease alone was 3.14. The highest invaliding and death rates were on the East India station. The total force serving afloat was 110,570. The total number of cases of disease and injury was 83,447, which is in the ratio of 754 per 1,000, a decrease of 118 per 1,000 as compared with the average of the last seven years. The total number of days of sickness on board ship and in hospital was 1,269,015, which represents an average of 11.47 days for each person, a decrease of 1.84 in comparison with the average of the last seven years. The total number of persons invalided was 2,511, which is in the relation of 22.7 per 1,000, a decrease of 7.28 in comparison with the average of the last seven years. Of the above total, 1,756 persons were finally invalided from the service, a ratio of 15.88 per 1,000 for the whole force, or 69.9 per cent. of the number invalided, a decrease of 1.16 per 1,000 when contrasted with 1903. Deaths numbered 493, a ratio of 4.45 per 1,000, which is a decrease of 1.91 per 1,000 as compared with the ratio for the last seven years. The average number of entries on the sick list for disease and injury per man was on the home station, 0.72 per 1,000.

Interesting Experiments on Schoolboys.

Interesting experiments have been carried out by the London County Council with the object of discovering the cause of variation in the physical condition of school children. Over 400 boys were weighed, measured, their teeth examined, and their personal cleanliness and clothing noted for the purpose of determining the conditions of their home life. An estimate of mental capacity was added by the teacher. Marks of from one to five were given to the boys after their clothing had been noted for evidence of the grade of poverty. In the first grade the clothing was of the scantiest possible. The boys were considerably below the average in weight, but the lack of height was not so marked. In the next grade the clothing was insufficient to retain animal heat. These boys worked out at the average. In the next grade the clothing was poor but passable; in the fourth it was good, and in the fifth very good. In the latter three grades the physical condition of the boys was above the average. Five per cent. of the boys were classified as dull and backward, 17 per cent. were below the average, 43 per cent. were of average intelligence, 24 per cent. were above the average, and 10 per cent. were brilliant. Curiously, these latter boys were slightly below the average in bodily conditions. Fifteen boys who lived in one-room tenements were slightly below the average weight, while their failure to come up to the average height was a little more marked. Those living in two and three-room tenements were of average height and weight. The boys living in four-room tenements were above the average in height and weight. One of the most potent causes of ill-nutrition was found to be the necessity of mothers leaving their homes to go to work. The majority of cases of injury to health were traced to want of cleanliness, and the provision of school baths as distinguished from swimming arrangements is declared to be increasingly necessary in many parts of London.

Pharmacology

Nostrums Advertised as Diuretics.

It is well known that the examination of the urine furnishes valuable clinical evidence in disease, and it is a case of a little knowledge being a dangerous thing so far as the layman is concerned, since he is told by those who advertise in the daily press that he may examine his own urine after it has stood twenty-four hours, "any sediment or cloudiness being proof of kidney disease."

Thus do these creatures, not content with preying on the sick, persuade the wily that they are hovering on the brink of the grave, with no chance of salvation save in the remedy recommended. These are among the most brazen swindlers and insidiously ordinary intelligence with such palpable fraud that they escape being considered criminals only by a shallow pretence or because our laws are woefully lacking in defining what constitutes a crime. The following paragraph from a daily paper well illustrates the really criminal suggestiveness of this class of advertisement:

"THIS SIMPLE TEST WILL TELL: Put some morning urine in a glass or bottle; let it stand for twenty-four hours. If it is milky or cloudy or contains a reddish brick dust sediment, or if the bottle or glass feels hot about it, if your kidneys are diseased,

This is the supreme moment when you should begin to take WAINMAN'S SAFE CURE to arrest all these unnatural conditions, for they are the unmistakable symptoms of kidney disease. If, after you have made this test, you have any doubt in your mind as to the development of the disease in your system, send us a sample of your urine, and our doctors will analyze it and send you a report with advice free."

ANASARIN AND SIMILAR PREPARATIONS.

To demonstrate that the methods employed by many men in the "ethical field" are little different from those of the "patent medicine" makers we call attention to a circular sent out by the Anasarin Chemical Co. For sublime effrontery and impudence the following is hard to match even in lay journals.

"In cases of valvular heart disease, when compensatory hypertrophy of the right ventricle is lost, and the patient is suffering all the distressing symptoms, headache, dizziness, vertigo, stupor, somnolence, dropsy with the most extreme dyspnea, that belongs to this stage of the disease and the physician in charge has used all the known remedies for such troubles, *i. e.*, digitalis, strophanthus, apocynum, spartein, supra-renal extract, etc., without avail, a few doses of Anasarin promptly relieves the dyspnea, the pulse is reduced in frequency, is more regular and full, and the dropsy begins to decline."

If the reader believes that the above is true, he must feel a feverish anxiety to learn the marvelous secret of the remedy. We are told that it consists of the active principles of *Oryzodendron arborescens*, *Sambucus canadensis* and squill.

The first named seems to occupy the same relative position to the nostrum that the "four legs" do in the riddle about the chicken "merely put in to make it harder to understand."

The proprietors of hydragogin make a statement which we hope no physician will accept. Hydragogin is said to consist of tincture of digitalis 1.5 parts, tincture of strophanthus 2.5 parts, scillipicin and scillitoxin, the active principles of *Scilla maritima* (how much?) and 0.5 part of oxyasaponin. The latter, which is extracted from *Herniaria glabra*, is said to increase the diuretic action of the first four many times, without any unpleasant by-effects. They immediately make this admission: "Of course, patients with individual peculiarities may, after some time, complain of malaise, weakness, anorexia or aversion to the drops, and in these cases it may be well to discontinue the drug for a time." We suspect that anasarin contains something closely akin to "oxyasaponin."

The confidence of the physician in anasarin is apt to be shaken when he reads further in the circular that "digitalis and squill are now known to contain alkaloids."

The circular of the Anasarin Chemical Co. affirms that in all their dealings they are guided by the highest standard of medical ethics. This latter statement may be true, but, if true, it is, indeed, a sad commentary on the present status of our sense of duty and propriety on matters relating to the very fundamentals of the practice of medicine.

"Patent Medicine" Legislation in Kentucky.

Representative Johnson of Franklin County has introduced a bill into the Kentucky legislature similar to the one adopted last year in North Dakota, providing that the formula of "patent medicines" be printed on the package. As far as we have been able to learn, the newspapers are not devoting any space to urging the passage of this law, nor do we hear of any efforts on the part of physicians or of the public to back up Representative Johnson in his efforts to check the "patent medicine" fraud in Kentucky. We do have evidence, however, that the "patent medicine" men are awake and very, very active. The effective principle underlying the "red clause" idea is being utilized.

We have been favored by a certain newspaper of Kentucky with letters which it has received from "patent medicine" firms and their agents, which make interesting reading and prove conclusively that even in Kentucky the nostrum men have, or think they have, their grip on the throats of the newspapers. Among these letters is a three-page letter from the Peruna people, signed—by rubber stamp—"S. B. Hartman," from which we quote:

"The millions of users of proprietary medicines make no demand for such a law. They have it in their power to use or not use the medicine. They are at least presumed to have enough common sense to know whether an article does them good or cures them and whether it does not. And most undoubtedly if it does not cure them they can at least protect them from its use, because they know the name of the article under which it goes."

This sounds extremely plausible, and certainly should be enough to convince any editor of the bigotry of those who would not allow the public to be their own judge as to whether they should take "patent medicine" or not. Several paragraphs are devoted to the editors of the *Ladies' Home Journal* and of *Collier's Weekly*. Dr. Hartman charges Mr. Bok with making a fight on "patent medicines" out of spite because one of the "patent medicine" firms has sued the *Ladies' Home Journal*. He says of physicians:

"These are the people who are crying for formulas on proprietary medicines, but when they are called on themselves to explain to the patient what they are giving them they would absolutely refuse to do so.

"Is this justice? Is this equity? In this free country of ours to preach a doctrine and to refuse to comply with this doctrine?"

"Dr." Hartman does not know, evidently, that the doctor's prescription is on file, to be referred to by the courts, if necessary.

"We would be pleased to have you take this up, immediately, with the senators and representatives of your state, either in person or by writing, and let them call the attention to the fact of the injustice and autocratic spirit of this act."

One of the letters is from a "patent medicine" advertising firm, and the writer is very pointed in his remarks regarding what will happen if the bill is allowed to become a law:

"When a similar bill was passed in North Dakota last year, we were obliged to cancel all our Advertising Contracts in North Dakota, and as other agencies did the same thing—the Newspaper people of North Dakota are standing the loss that was brought about by some Country Doctor losing a fee on account of one of his patients buying a bottle of Castoria. These Country Doctors are so narrow between the eyes that they 'can look through a key hole with both eyes at one time.' . . . The writer feels that he knows the physician a little bit better than the average advertising man; because, in the first place, he spent twenty years of his life in the Wholesale and Retail Drug business, and his dealings during this time were confined mostly with physicians, and he can go on record in saying that during all this time he actually never knew of a case of where a Doctor stayed up nights studying how he could improve the health of a Community at large."

Here is a paragraph, however, that is too good to let pass:

"Now, let us tell you another thing, if the Doctors in the United States did not prescribe Proprietary Medicines one-half of the Manufacturers of these remedies in this Country would go out of business inside of twelve months."

Physicians who are in the habit of prescribing nostrums should read this sentence two or three times, and, if possible, should learn it by heart. Of course, it must be remembered that the writer of the letter is talking about "patent medicines," but he dignifies them with the title, "proprietary medicines."

The Hostetter Company, proprietors of "Hostetter's Stomach Bitters," gives a hint to the newspaper addressed in these words:

"We would, therefore, kindly urge you to use your best efforts with your Representative to assist in defeating it, otherwise we will be compelled to withdraw our advertising from the various newspapers throughout the State."

The Chattanooga Medicine Company is the firm that puts out "Wine of Cardui," the advertisements of which are so insistent that no man with any self-respect would dare to read them out loud before his family. This company also writes a letter to the newspaper and covers the same old arguments. Here is one:

"Last summer a letter was published by Edward Bok, editor of the *Ladies' Home Journal*, in which he gave the physicians to understand that he had organized a bureau to promote legislation of this character and that bills for this purpose would be forthcoming in every state legislature during the coming winter. It may, therefore, be assumed that the inclosed bill is the one which the editor of the *Ladies' Home Journal* deems most suitable for the people of Kentucky and which he has caused to be introduced."

Poor Mr. Bok seems to be "getting it in the neck" sadly. As it happens, however, this is not Mr. Bok's bill, if he has any, and Mr. Johnson, we are reliably informed, knows nothing about the articles in the *Ladies' Home Journal* or about the bill with which Mr. Bok is credited.

We make one more quotation from the "Wine of Cardui" people:

"Trustworthy statistics gathered during the last six months conclusively show that casualties from the use of proprietary medicines are everywhere and practically never occur when the directions on the package are followed. On the other hand the number of fatalities arising from the use of strychnin, morphin, arsenic, etc., prescribed by physicians, is many times greater than the casualties resulting from the use of proprietary medicines of every description."

It may be interesting to note that this paragraph occurs almost word for word in the letter of the "Peruna" people and that the same "arguments" are given in all the letters, indicat-

ing a common source for the "information" that is supplied to the servile newspapers.

A desperate effort is being made by the press committee of the Proprietary Association, assisted by the *Western Druggist* of Chicago, the *National Druggist* of St. Louis, and some other drug journals, to overcome the verified statements of Mr. Adams regarding deaths from the use of "patent medicines," but they have not succeeded. We hope to have something definite to say on this point before many weeks. From evidence that has been coming into this office recently, Mr. Adams did not by any means exaggerate when he spoke of the number of deaths from the use of "patent medicines"; he most decidedly underestimated the number.

There are other letters of a similar tenor, but we have quoted enough to show that the tactics to muzzle the press, as illustrated in *Collier's* article on "The Patent Medicine Conspiracy Against the Freedom of the Press," and that were used in Massachusetts and in Wisconsin, are being adopted in Kentucky.

This brings up the question: Who is representing the public in this matter, and what are the physicians of Kentucky doing about it? Thus far, physicians have done nothing in furthering the propaganda against the "patent medicine" fraud, probably because they fear that if they did their motives would be misconstrued and their actions charged to selfishness.

The Proprietary Association is asserting that physicians are instigating this fight against secrecy and fraud in "patent medicines"—for it is the secrecy and fraud that are objected to, this must not be forgotten—therefore, since we have the credit, would it not be just as well for us to deserve this credit and go to work and do what we ought to do? We urge the physicians of Kentucky to assist in this fight against the vultures who are preying on the gullibility of the ignorant and on the fears of the sick and the suffering.

Endorsement of the Propaganda Against the Nostrum Evil.

At a meeting of the New York Academy of Medicine, held January 18, the following resolution was offered, seconded and, after some discussion, passed:

WHEREAS, The evil caused by the widespread use of preparations of drugs of unknown and deleterious constituents indicates a very great and growing injury on a large proportion of the public, and

WHEREAS, It is impossible to overcome this evil by individual effort because the preposterous and extravagant claims made by their purveyors are convincing to the uninformed by reason of the media of their advertisement, which include periodical literature of all descriptions, not only the daily press and magazines, but also religious and otherwise reputable medical journals and many countless imitations of the latter, to some of which an income practically amounting to a subsidy is plain; and

WHEREAS, Physicians frequently aid in the propagation of the evil by prescribing them, by giving testimonials in favor of them, or indirectly, by their failure to prescribe according to the needs of their individual patients, therefore be it

Resolved, That this academy urges most strenuously on its fellows and on all other physicians, never under any circumstances to sanction the use of any preparation the nature and quantity of whose ingredients are unknown to them, whether it appear in the guise of medicine, a food or as an application for external use; and to this end to prescribe definitely, exactly and in writing for every patient who needs any drug or combination of drugs; to diffuse among the laity as widely as possible a knowledge of the nature and quantities of the preparations of drugs of unknown constituents; to second as far as possible the efforts of the American Medical Association in its attempt to combat this evil through the agency of its Council on Pharmacy and Chemistry, whose duty it is to investigate medicinal preparations and to publish the truth about them; and to use all proper influence to have advertisements of them removed from medical journals;

Resolved, That pending repressive legislation which is likely soon to take place in many state legislatures and also in Congress, the attention of the State Board of Health be respectfully directed to the admirable chemical work which has been conducted for years by the Massachusetts State Board of Health and which has resulted in the filing in the Massachusetts State House of a long list of compounds, with their preparations, which have been found to contain amount of their noxious ingredients; and that the Department of Health of this city be respectfully urged to exercise its powers to protect the public against the dangers of secret preparations of all sorts, which are now known to be used, and which have already been shown to be so, by absolutely prohibiting their sale within the limits of its jurisdiction;

Resolved, That wide publicity be given to these premises and resolutions under the direction of the council and that attested copies of them be sent to the boards of health of this state and of this city.

At a meeting held January 11 the Montebm County (Mich.) Medical Society adopted resolutions endorsing the work of the Council on Pharmacy and Chemistry in investigating non-official drugs and in educating the medical profession concerning the evils of secret nostrums. The society declared that as

physicians have the right to know the composition of all remedies used by them it is their duty to refrain from using articles for which the formulas are not given. The society also commended the work of the *Ladies' Home Journal* and *Collier's Weekly* in exposing "patent medicines."

Similar resolutions were passed by the Crawford County (Ill.) Medical Society, the Allamakee County (Iowa) Medical Association, the Santa Barbara County (Cal.) Medical Society, the Atlantic County (N. J.) Medical Society, and the New Castle County (Del.) Medical Society.

The Shelby County (Ala.) Medical Society, at a meeting held January 9, passed resolutions approving the work of *THE JOURNAL*, and of the Council on Pharmacy and Chemistry in exposing secret remedies, and also the work of the *Ladies' Home Journal* and *Collier's Weekly*. In addition, the members of the society pledged themselves not to prescribe any preparation of which the formula and proportions of the ingredients are not well known and substantiated by well-accepted medical authorities. The society also condemned unqualifiedly all religious publications which publish advertisements of deleterious "patent" preparations, or snare cures for cancer, dropsy, tuberculosis or Bright's disease.

The Utah County (Utah) Medical Society endorsed the action of the American Medical Association and instructed the secretary to notify the Utah State Medical Association, the American Medical Association and the Utah State Pharmaceutical Association to that effect and also to advise these bodies that the society has sent a petition to Congress in support of Senator Heyburn's pure food bill.

One Illustration of the Danger of Using a Nostrum.

In the January number of the *Medical World* is an illustration of what can happen, and often does happen, when a physician prescribes a secret preparation. Some one contributes an article on the treatment of pneumonia, but the editor generously suppresses the name of the author. The latter claims to have practiced thirty years, "hoping all that time that I should some time be a doctor; but I am yet a student." For "pain or stitch in side," he gives a hypodermic of morphia, and adds:

"This gives perfect ease with deep breathing. At this stage I am not afraid of acetanilid. I generally carry a preparation made as follows:

"R. Acetanilid 3i
"Soda bicarb.

"Bromo seltzer, aa 3ss
"M. Triturate thoroughly. Dose, 5 gr. to 15 gr.

"Follow the hypodermic with a dose of the above mixture. In from 20 to 60 minutes the patient begins to complain. 'Oh, I am so hot!' A few minutes later a copious sweat sets in. Your patient is now comfortable."

The last remark is not to be wondered at, and it would not be strange if the patient remained "comfortable" for a long time. As the editor of the *Medical World* comments, "It is no wonder that his patients become cyanosed and suffer from drenching sweats." Here is a doctor mixing this nostrum, bromo-seltzer, a principal ingredient of which is acetanilid, with acetanilid. He is a student, he says, and we hope that he will prove to be one to the extent at least of learning not to prescribe anything unless he knows exactly what he is prescribing.

A Pertinent Question.

The *Medical World*, commenting on one of the *Collier's* articles on nostrums, concludes with this pertinent question:

"How can the editor of any medical journal read the exposé of antikamnia above mentioned and print the advertisement of antikamnia in his advertising pages? The profession should ask every medical editor if he has read the article above referred to, and then ask why he carries the antikamnia advertisement. Will you write to the editors of all the medical journals you take about this matter?"

But why not ask the same question regarding ammonol, salicobia (Bell) and phenalgin? They are all in the same category. It is not only because it is indirectly advertised to the public that antikamnia should be condemned, but because it is a dangerous nostrum that has been foisted on our profession on false claims. The other acetanilid mixtures we mention should be refused recognition for the same reasons.

A Pharmaceutical Secret Which Should Not be Lost.

Dr. Gregory Costigan, New York City, writes, under date of January 21, as follows:

"I have been carefully reading and enthusiastically approving your articles on the nostrum evil, and have been impressed more than usual on the existence of quack advertising in medical journals as set forth in last paragraph and quotation on page 206, bottom of first column, of your issue of Jan. 20, 1906.

"In *Merkel's Archives*, page 11, we are told in an advertisement on 'Phenalgin' that it is a compound of peculiar character which can not be extemporaneously made from powdered drug and 'our process of manufacturing tablets is coincident with the manufacture of Phenalgin and is the result of a long series of careful experiments by which we are able to produce tablets of Phenalgin in a friable condition without losing any of its volatile constituents or undergoing chemical changes from heat or moisture'!! Inasmuch as Phenalgin tablets are not covered with a waterproof coating I think this is a remarkable statement to make, and the manufacturing of a drug coincident with the manufacture of a tablet must be a very remarkable performance especially because it 'retains the full therapeutic value of the drug unimpaired' while the advertisement asserts that no other manufacturer is cognizant of this wonderful method. This ad. is for the perusal of physicians only. The Etna Chemical Company owes it to the medical and pharmaceutical world not to let this secret die with the company's dissolution. It owes it as a duty to the coming generations of science immediately to jot down the full data of this wonderful performance, to put it away in an age-proof safe and not to allow it to be lost to humanity as were a great many other arts that were well known to the ancients. Let them keep it secret now and profit by it, but do not let it be lost to posterity."

Correspondence

The Index Medicus.

WASHINGTON, D. C., Jan. 15, 1906.

To the Editor:—The complimentary dinner given in honor of the approaching 83d birthday, on March 6, 1906, of one of the founders and the principal editor of the *Index Medicus*, Dr. Robert Fletcher, has naturally directed attention to that publication.

The *Index Medicus* is a monthly publication, issued under the auspices of the Carnegie Institution of Washington, D. C. It is edited by Dr. Robert Fletcher and Dr. Fielding Garrison, of the Library of the Surgeon-General's Office. It is just what its name indicates, a medical index, or subject and author catalogue of all the current medical literature of the world of the preceding month.

It is compiled, through the courtesy of Dr. Robert M. O'Reilly, Surgeon-General, U. S. Army, and Major Walter McCaw, Assistant Surgeon-General and Librarian of the Library of the Surgeon-General's Office, from the cards prepared for the "Index Catalogue of the Library," the cards being loaned for that purpose. The "Index Catalogue" is published in progressive volumes, one volume a year, covering one or more letters of the alphabet, according to the number of titles that can be comprised in the prescribed 1,000 pages of the volume.

The *Index Medicus* was founded by Drs. J. S. Billings and Robert Fletcher in 1879, who were its editors until Dr. Billings retired from the Medical Department of the Army. From 1879 to 1884 it was published by F. Leybold, of New York. It then announced its suspension for want of sufficient support, but, with the beginning of 1885, George S. Davis, of Detroit, took up the publication and continued it until 1895. From May, 1895, until April, 1899, the publication was issued by the editors, when it suspended publication. Jan. 1, 1903, the Carnegie Institution undertook the responsibility of publication.

Although Dr. Fletcher was in his 81st year when the Carnegie Institution undertook the publication, and was reluctant again to take up the editorship, he yielded to the urgent persuasions of his many medical friends and again resumed the editorial chair, assisted by Dr. Fielding Garrison, who has been for some years associated with Dr. Fletcher in the compilation of the "Index Catalogue."

The subscription price of the *Index Medicus* was originally \$5 per year, but at this price the publishers lost money. It was then raised to \$10, but this was not sufficient to pay the enormous cost of printing, and \$25 a year was subscribed by one or two hundred enthusiastic medical writers, but even this was not sufficient to meet the growing expense.

It may readily be asked why so valuable a publication was not self-supporting. The answer is that in the entire medical profession there are only a comparative few who are interested to any extent in medical research, but more particularly to the fact to those only who have easy access to large medical libraries or who could afford to come to Washington and use the Library of the Surgeon-General's Office would the *Index* be of much service, as it gives only the titles of books and journal articles and the source from which they are taken. But to those who are engaged in medical research, and wish to keep in touch with the very latest and best thought and progress of medicine and surgery it is considered invaluable and indispensable.

THE INDEX CATALOGUE.

The "Index Catalogue of the Library of the Surgeon-General's Office," which forms the basis of *Index Medicus*, is the most perfect and complete author and subject index ever published.

The first series of this magnificent government publication, comprising 16 large quarto volumes, from A to Z, began in 1880, and ended in 1895. In 1896 letter A of the second series was begun, and last fall vol. x, containing only part of letter M, was issued. Only one volume is published each year.

The publication contains an author and subject index to about three-fourths of all the medical and surgical literature of the world for all time, and about 90 per cent. of the literature for the past twenty years. It differs from the *Index Medicus* in that it contains everything, old or new, to be found in this great national library, while the *Index Medicus* only contains the new and current literature. A word or two will make it clear as to why the *Index Medicus* was deemed necessary.

As the "Index Catalogue" is published progressively, one or two letters of the alphabet at a time, it is manifestly obvious that it could not keep up with the current literature. For example, a physician who wishes to write a paper or examine into the literature of tuberculosis for the past ten or twelve years can get his references from the *Index Medicus*, whereas he would have to wait until about the year 1909 for the volume of the "Index Catalogue" containing that subject, or else come to Washington and consult the card catalogue. The *Index Medicus* obviates that difficulty, and it was for this reason it was begun as a private undertaking. But this would have been an impossibility had it not been, as I have stated, for the courtesy of the Surgeon-General in permitting the publishers to have access to the cards which were daily being indexed for the "Index Catalogue."

The classification of subjects in the *Index Medicus* necessarily differs very materially from that of the "Index Catalogue," which is more minute and covers a broader range, yet it is a most comprehensive classification, and to many of the users of both the former is very satisfactory and easily understood.

To Dr. Robert Fletcher, principal assistant librarian and chief editor of the *Index Medicus* during its entire existence, is due the credit of this most perfect work, but it would be difficult for any one to comprehend fully the vast amount of painstaking labor involved. Night after night and month after month during these 23 years he has burned the midnight oil in order that the medical profession should have their beloved index in all its perfectness on the day of publication. Had he not been the most methodical and systematic worker engaged in any literary work, he would long ago have broken down under the great strain. Not the slightest detail of arrangement or classification or typographical execution but what came under his rigid scrutiny. It was a peculiar task, requiring much thought and a perfect encyclopedic knowledge of medical nomenclature, a faithful attention to detail and unceasing toil and vigilance. The last revised proof sheets of the index, as they left his hands each month for the office of publication, formed, in fact, a miniature monthly edition of the

great "Index Catalogue," which has been and still is the wonder of the world. It brought to its few appreciative subscribers a perfectly classified index of the original writings of all the medical men of the world on every subject in medicine and surgery for the past month, and at the end of each volume it contained an author and subject index to every book and journal title, which of itself was a marvel of painstaking labor. The author index was particularly valuable for reference, furnishing, as it did, a complete bibliography of the writings of all medical men, whether of a book or a journal article.

HARRY O. HALL,

In Charge of Reading Room,
Library Surgeon-General's Office.

Medical Student Reputations.

BUFFALO, N. Y., Jan. 13, 1906.

To the Editor:—Alluding to your editorial in THE JOURNAL, January 13, on "Medical Student Reputations," allow me to point out that the whole trouble as to student rowdism is of comparatively recent date and practically synchronous with the development of social life analogous to that at colleges. A small boy apologized for his too demonstrative puppy that he didn't know he was a dog, he thought he was folks. Exactly the same trouble ails our too demonstrative medical, law, pharmaceutical, veterinary and other professional students and, ridiculous as it may seem, even callow, ignorant boys making up deficiencies of arithmetic and learning bookkeeping and stenography at business "colleges."

All these boys are impressed with the notion that they are college students. If they have to spend their time on less ornamental and more immediately practical things than Latin and Greek and calculus and geology, they can, nevertheless, parade in their nightshirts or break in the doors of the college, or sing snuffy songs about the faculty at a theater party.

Now, I haven't a word to say in extenuation of similar doings by real college students and I would not like to admit that the man who is preparing for lifework in a profession, is not engaged in a highly reputable and honorable occupation. There is not even any objection to calling a quiz society by Greek letters or having a sofa pillow with college colors on it, or maintaining a football team or in other reasonable ways copying at professional schools, the social life at colleges.

But, when in the attempt to make a "college" man of himself, the professional student indulges in foolish and destructive acts, the time has come not to appeal to his sense of honor or maturity, or to his realization of the dignity of his future profession, but to get at the root of his self-deception. Snobbishly if need be, plainly in any case, set it before him that he thinks he is folks when he is just plain dog. Let him understand that a professional school is not a college and that his lawless acts will not be covered by the mantle of glamor and social prestige which, rightly or wrongly, sometimes cover similar lawless acts by the genuine article.

A. L. BENEDICT, M.D.

A Simple Method of Making a Blood Count.

BALTIMORE, JAN. 16, 1906.

To the Editor:—I have a clinical suggestion to offer your readers which I have found valuable. It is so simple that it may be a very common procedure, but if so I am not aware of the fact. In the Thoma Zeiss blood-counting apparatus the lines on the counting scale which may be seen plainly under the microscope when there is no blood on the slide do not always show out clearly when the drop of blood has been covered with the cover slip and the slide made ready for the examination. In accurate work, when a large number of fields are counted, a great deal of time is lost, in the aggregate, in getting the proper portion of the slide under the lens, especially when the higher powers are used. For some time I have used a method which, while very simple, is not mentioned in textbooks, and is not only a time saver, but also renders the blood count more accurate, as less manipulation of the slide is

required. The examiner places the slide under the microscope and gets the counting field in place, and then takes a lead pencil and outlines the slide on the stage of the microscope. Whenever one wishes to count a field, one has merely to insert the slide in this space of outlined area and the field is always directly under the lens ready to be counted. A great saving of time and patience is effected by this simple procedure, which means a great deal at the end of a week or month to those who make many blood examinations. The directions are simple: Draw the outline of the slide on the stage of the microscope when the counting field is in view. When, therefore, one wishes to count a field the slide is placed in this outlined area and the counting field is exposed at once.

B. B. BROWNE, JR., M.D.

Marriages

EDMOND DOAK, M.D., to Miss Ethel King, both of Taylor, Texas, January 17.

HERBERT PEASE, M.D., Slater, Iowa, to Miss Lois Felshaw of Collins, Iowa, January 17.

EMMA S. POWELL, M.D., and Frank W. Hill, both of Ottumwa, Iowa, January 10.

J. C. CUTLER, M.D., Belkville, Wis., to Miss Jessie McMore of Verona, Wis., December 28.

JESSE EDWARDS HUNT, M.D., to Miss Marion Ingalls, both of Atkinson, Kan., January 25.

JOSEPH H. VOGEL, M.D., to Miss Antoinette Crone, both of New Utm, Minn., January 24.

A. M. WYLIE, M.D., Chester, S. C., to Miss Lizzie Hardeman of Louisville, Ga., January 24.

GEORGE W. KOCH, M.D., Akron, Iowa, to Miss Frances Gilbert of Geneseo, Ill., January 1.

P. McHUGH WALKER, M.D., to Miss Mabel Garnett, both of St. Thomas, N. D., January 10.

ROBERT W. HALE, M.D., to Miss Cora Bowman, both of Thermopolis, Wyo., December 23.

LOUIS WEISS, M.D., Newark, N. J., to Miss Henrietta Epstein of New York City, January 11.

CHARLES A. UNDERWOOD, M.D., Warsaw, Ind., to Miss Clara Moore of Covington, Ind., January 24.

HARRY E. DOWNS, M.D., Batson, Texas, to Mrs. Sarah E. Potter of Beaumont, Texas, January 11.

ANDREW D. HOIDALE, M.D., Tracy, Minn., to Miss Pauline Madeira of New Utm, Minn., January 9.

DAVID CUMMINS MORTON, M.D., to Miss Mary Harris Ballard, both of Louisville, Ky., January 25.

R. T. VAN METRE, M.D., Dewar, Iowa, to Miss Marie C. Murdock of Kewanee, Ill., at Iowa City, January 17.

FRANK R. MILLER, M.D., Everett, Wash., to Miss Daisy Wright of Canton, Ill., at Galesburg, Ill., January 10.

JOHN A. COPELAND, M.D., Coleridge, Neb., to Miss Laura McKay of Sioux City, Iowa, at West Side, Iowa, January 10.

Deaths

Emerson Warner, M.D., Harvard University Medical School, Boston, 1863; for twenty-five years consulting surgeon at Worcester City Hospital; since 1871 consulting surgeon to the Memorial Hospital; for 17 years a member of the attending staff of the City Hospital; for many years president of the Worcester District Medical Society, and councillor of the Massachusetts Medical Society; a member of the legislature in 1881 and 1885; and for twenty years a member of the local school board, died at his home in Worcester, December 30, from endocarditis, after an invalidism of twenty years, aged 71.

Swan Moses Burnett, M.D., Bellevue Hospital Medical College, New York City, 1870; Ph. D. Georgetown University, 1890; a member of the American Medical Association, Washington Academy of Sciences, and American Ophthalmological Association; professor of ophthalmology and otology, University of Georgetown; professor of ophthalmology, Washington Postgraduate Dispensary and Emergency Hospital; ophthalmic sur-

geon to Providence and Children's hospitals, Washington; a prolific writer on ophthalmologic subjects, died suddenly at his home in Washington, D. C., January 18, from heart disease, aged 58.

Hiram S. McConnell, M.D., Bellevue Hospital Medical College, New York City, 1875; a member of the American Medical Association, Medical Society of the State of Pennsylvania, Western Pennsylvania Medical Association, and Beaver County Medical Society; for three terms a member and secretary of the State Board of Medical Examiners; for twenty years a member and most of that time president of the New Brighton board of education; a very prominent practitioner of the Beaver Valley, died at his home in New Brighton, Pa., January 15, from pneumonia, after an illness of four days, aged 57.

George Chismore, M.D., Medical College of the Pacific, San Francisco, 1873; a member of the American Medical Association; medical officer of the American division of the Western Union Russian-American extension from 1865 to 1867; acting assistant surgeon, United States Army, on frontier duty from 1867 to 1872; one of the foremost surgeons of the Pacific Coast, died at his home in San Francisco, January 12, from pneumonia, after an illness of five days, aged 65.

James D. Wright, M.D., Medical College of Ohio, Cincinnati, 1855; once a member of the Iowa legislature; one of the organizers of the State Board of Agriculture and a trustee of the State Agricultural College at Ames; surgeon of the Forty-seventh Iowa Volunteer Infantry in the Civil War, died suddenly at the home of his son in Chariton, Iowa, December 26, from cerebral hemorrhage, aged 85.

John F. Miller, M.D., Jefferson Medical College, Philadelphia, 1858; superintendent of the State Hospital at Goldsboro, N. C., for the colored insane; surgeon of the Twenty-fourth North Carolina Infantry, C. S. A., in the Civil War, died suddenly at his residence in Goldsboro, January 9, from heart disease, aged 71.

Oswald M. Justice, M.D., College of Medicine and Surgery of the University of Minnesota, Minneapolis, 1897; formerly of Elysian, Minn., and coroner of Le Sueur County; convicted of crime in California and sentenced to six years' imprisonment, committed suicide in his cell by strangulation recently.

Stansmore Vivian, M.D., Bellevue Hospital Medical College, New York City, 1885; attending physician at the Iowa County (Wis.) poorhouse; chairman of the school board of Mineral Point, died at his home in that city from cerebral hemorrhage, January 4, after an illness of a few hours, aged 46.

Harry A. McGronen, M.D., Illinois Medical College, Chicago, 1898, of Brooklyn, N. Y., assistant dermatologist in the Brooklyn Central Dispensary, was instantly killed January 12, by being crushed by a freight elevator in a department store in New York City, aged 35.

B. Franklin Watkins, M.D., Department of Medicine of the University of Pennsylvania, Philadelphia, 1852; surgeon in the Confederate service during the Civil War; for many years a practitioner of Bryan, Texas, died at his home in that city, December 25, aged 73.

Charles Nelson Miller, M.D., Bellevue Hospital Medical College, New York City, 1883; an active member of the Morris District Medical Society and of the Tri-county Medical Society, died at his home in German Valley, N. J., from nephritis, January 14, aged 43.

Simeon T. Yancey, M.D., Medical College of Indiana, Indianapolis, 1874; state senator from Hancock County, Ind., from 1880 to 1882; state oil inspector in 1884; a veteran of the Civil War, died suddenly at his home in Fortville, Ind., January 4, aged 70.

S. D. Dodge, M.D., Jefferson Medical College, Philadelphia, 1866, at one time physician to the Arkansas School for the Blind, Little Rock, died at the home of his sister in that city, January 9, from bronchopneumonia, after an illness of eight days, aged 65.

William M. Hill, M.D., for more than forty years a practitioner of Hopkinsville, Ky., twice chairman of the board of council, and for several years a councilman, died at his home in Hopkinsville, from senile debility, January 15, aged 78.

Thomas Austin Harris, M.D., Louisville Medical College, 1881; formerly of Rosedale, Miss.; a member of the American Medical Association, and state, tri-state and county societies, died recently from dropsy in Tishomingo, I. T., aged 48.

Clark R. Warren, M.D., Rush Medical College, Chicago, 1876, a veteran of the Civil War, and for many years a practitioner of Otis, Ind., died at his home in Chicago, January 2, from brain tumor, after an illness of eight weeks, aged 65.

Richard Armstrong Heath, M.D. University of Edinburgh, Scotland, 1891, of New York City, died at St. Luke's Hospital, New York City, from pneumonia, January 17, four days after a fall from a street car in which his shoulder was injured, aged 42.

Charles L. Webster, M.D. College of Physicians and Surgeons of Chicago, 1894, a member of the Cleveland Academy of Medicine, died at his home in Cleveland, December 22, from cancer, after an illness of six months, aged 43.

William I. Wallace, M.D. University of Michigan Homeopathic Medical College, Ann Arbor, 1884, died from consumption at his home in Hemet, Cal., December 14, after a prolonged illness, aged 42.

Wellington B. Briggs, M.D. University of Nashville (Tenn.) Medical Department, 1862, secretary of the Brazos Valley Medical Association, was found dead in his home in Easterly, Texas, January 14.

J. Lee Beck, M.D. Boston University School of Medicine, 1879, of Vineland, N. J., was struck by a train and instantly killed, January 18, while driving over a grade crossing near Norma, N. J.

Isaac Cooper, M.D. Hahnemann Medical College, Philadelphia, 1868, died at his home in Trenton, N. J., January 17, from cerebral hemorrhage, after an illness of three days, aged 61.

George W. Watkins, M.D. (33 Years' Practice), Kentucky, 1893, a practitioner of Spottsville, Ky., for 45 years, died from senile debility at his home in that place, December 21, aged 78.

Benjamin Liles Askew, M.D. (Twenty-five Years' Practice, Ohio, 1890), a veteran of the Civil War, died suddenly at his home in Jefferson, Ohio, from heart disease, January 7, aged 71.

Joseph T. Clymer, M.D. Eclectic Medical Institute, Cincinnati, 1886, died at his home in Monticello, Ind., January 10, from acute gastritis, after an illness of a few hours, aged 53.

Henry S. Foster, M.D. Jefferson Medical College, Philadelphia, 1892, of McKeesport, Pa., died in the hospital in that city, January 13, from the effects of an overdose of morphin.

Augustus S. Wright, M.D. Hahnemann Medical College, Philadelphia, 1850, died at his home in Santa Rosa, Cal., December 22, from pneumonia, after an illness of three days, aged 80.

Joseph D. Hoare, M.D. New York University, New York City, 1887, of Brooklyn, N. Y., died at the Steuben Sanitarium, Hornellsville, N. Y., January 9, after a long illness, aged 40.

Philip F. Lightfoot, M.D. Years of Practice, Illinois, 1887, a veteran of the Civil War, died at his home in Murrayville, January 14, shortly after a fracture of the hip, aged 82.

William Bonnell Hall, M.D. Department of Medicine of the University of Pennsylvania, 1855, a Confederate veteran, died at his home in Lowndesboro, Ala., January 14, aged 71.

Henry W. Whitfield, M.D. University of Nashville (Tenn.) Medical Department, 1858, died at his home near Bakerville, Tenn., January 6, after a short illness, aged 74.

James F. Logan, M.D., a practitioner for about fifty years, died at his home in Clarksville, Iowa, January 6, from influenza, after an illness of two weeks, aged 78.

William M. White, M.D. Albany (N. Y.) Medical College, 1886, died at his home in Amsterdam, N. Y., from pneumonia, December 29, after a short illness, aged 49.

Willard T. Greenfield, M.D. Miami Medical College, Cincinnati, 1882, of McKean, Pa., died at his father's house in Erie, Pa., January 5, from heart disease, aged 46.

Melite E. Chartier, M.D. University of Paris, France, died at Biloxi, Miss., where he had practiced for many years, January 7, from alcoholism, aged about 50.

Jacob A. Heller, M.D. Jefferson Medical College, Philadelphia, 1881, died suddenly at his home in Factoryville, Pa., January 12, from heart disease, aged 55.

Philip S. Orndorff, M.D. (Years of Practice, W. Va.), a Confederate veteran, died at his home in Rio, W. Va., January 16, from paralysis, aged 72.

William E. Hodges, M.D. University of Maryland School of Medicine, Baltimore, 1856, died at his home in Ellicott City, Md., January 16, aged 75.

William C. Poe, M.D. University of Maryland School of Medicine, Baltimore, 1865, died at his home in Baltimore, January 20, aged 62.

William Armstrong, M.D., member of the College of Physicians and Surgeons of Ontario, 1869, died at Toronto, January 11, aged 79.

James Christopher Deaton, M.D. Medical College of Virginia, Richmond, 1868, died at his home in Richmond, Va., January 12.

James H. DeWolf, M.D. Jefferson Medical College, Philadelphia, 1878, died at his home in Baltimore, January 17, aged 51.

William H. Bright, M.D. Rush Medical College, Chicago, 1865, died at his home in Martinsburg, Ind., January 13, aged 74.

Deaths Abroad.

C. L. van der Burg, M.D., of Utrecht, Holland, died recently, aged 66. He practiced in the Dutch East Indies for more than twenty years, and his works on the medical-geographic pathology of the East Indies and tropical diseases in general are accepted as standard authorities on the subject. He had been the editor of *Janus* since the death of its founder, Peypers, about a year ago.

Karoline Knur, M.D., Frankfurt on the Main, assistant physician to the public insane asylum, one of the first medical women to qualify in Germany and the first to devote herself to psychiatry, died recently, aged 39.

K. Hodlmoser, M.D., one of the collaborators on the *Wien. klin. Rundschau*, and author of a number of articles on internal medicine, died at his post in Sarajevo, Austria, early in January.

H. Rabi-Ruckhard, M.D., professor of anatomy at Berlin and author of a number of works on comparative anatomy and simulation of ocular disturbances, died at Berlin, December 20, aged 67.

H. Schmaus, M.D., professor of pathologic anatomy at Munich, and author of text-books on his specialty, died at Munich, December 12, aged 43.

E. Kusy von Dubrav, M.D., chief of the sanitary service in Austria, died at Vienna, Dec. 19, 1905, aged 61.

P. Jacobs, M.D., the senior of the physicians of Germany, died at Cologne, January 2, aged 96.

A. Sachsasber, M.D., professor of ophthalmology at Graz, died December 22, aged 41.

F. Hirsch, M.D., professor of ophthalmology at Basle, died recently, aged 58.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish name or address will be faithfully observed.

MEDICAL DICTIONARY—RECIPROCITY WITH OHIO AND WEST VIRGINIA.

W. VA., Jan. 17, 1906.

To the Editor:—(1) What is probably the best and most nearly "up-to-date" medical dictionary for the use of the general practitioner? (2) What states have reciprocity agreements with Ohio and West Virginia boards?

J. H. B.

ANSWER.—Gould's (Blakiston Co., \$10 net); or Dorland's (Saunders & Co., \$5). (2) With Ohio: Indiana, Illinois, Maine, Michigan, Nebraska and Wisconsin. With West Virginia: None.

State Boards of Registration

COMING EXAMINATIONS.

NEW YORK State Boards of Medical Examiners, Albany, January 30-February 2. Secretary, Charles F. Wheelock, Albany.

NEBRASKA State Board of Health, State House, Lincoln, February 7-8. Secretary, George H. Brash, Beatrice.

California December Report.—Dr. Charles L. Tisdale, secretary of the Board of Medical Examiners of the State of California, reports the written examination held at San Francisco, Dec. 20-22, 1905. The number of subjects examined in was 9; total number of questions asked, 90; percentage required to pass, 75. The total number of candidates examined was 80, of whom 37 passed and 43 failed. The following colleges were represented:

	PASSED.	Year Grad.	Per. Cent.
Cooper Med. Coll.	(1905)	75, 75.5, 78,	82.4

Florida Examination Questions.—At the examination held by the State Board of Medical Examiners, at Jacksonville, October 10-11, 1905, the following questions were asked:

ANATOMY.

1. What bones form the roof of the mouth? 2. Give the number of the bones and name the regions of the spine. 3. What muscles form the calf of the leg? 4. Mention the cavities and valves of the heart. 5. What arteries unite to form the basilar artery? 6. Give the average length of the alimentary tract and state its chief divisions. 7. What is the prostate gland and where is it situated? 8. Name the glands and where are they found? 9. Mention the coverings of the brain. Describe one of these coverings. 10. Mention the lobes of the liver and describe one of them. 11. What veins convey arterial blood?

PHYSIOLOGY.

1. How many heart sounds are there, and to what are they due? 2. Describe the changes in the blood under goes in passing through the lungs. 3. Give the composition of human milk. 4. Define digestion and enumerate its stages. 5. Define excretion and excretion. 6. What is the function of the retina? 7. Describe the fetal circulation. 8. Give the physiology of menstruation. 9. Give the specific gravity of urine. 10. What do you know of the functions of the spleen?

SURGERY.

1. What is pus? Of what is it produced and by what symptoms can you determine its presence in tissues? 2. What is a wound? Give a general classification of wounds. 3. Describe the conditions of injury to a member or limb that would justify if not demand amputation. 4. When serious wounds are sustained, what symptoms should first engage the attention of the surgeon? How would you combat these symptoms? 5. In ligation of superficial femoral artery, how would you avoid injuring what important vessel? What would be the results of such injury? 6. What would you do for

complicated fracture involving the elbow joint? 7. Name briefly the common but important preparation for a modern operation: Preparation of the patient (3); of part to be operated on (3); of operator and assistants (2) and of instruments and appliances (2). 8. Name different methods of amputation. Which would you adopt in amputation of thumb at carpo-metacarpal articulation? 9. With following history of injury, what symptoms would you expect and how would you treat such a patient: A severe blow with stick or piece of timber in region of left parietal bone followed by considerable induration of scalp and a marked indentation of cranium? 10. What important tissues and organs would be wounded and how treat the following wound made by a .38-caliber pistol ball: Called within ten minutes, find patient bleeding copiously, locate and remove the projectile, entrance 1 inch below and 1 inch to right of right nipple; wound of exit just below 11th rib and near point of 12th rib posteriorly on same side?

GYNECOLOGY.

1. Describe briefly the Fallopian tubes. 2. What is meant by ectopic gestation? 3. At what age does the menstrual function become established? When does it cease and what is this cessation called? 4. Give treatment for retroversion of the uterus. 5. What is the average depth of the normal uterus? 6. Give symptoms and treatment of pelvic peritonitis. 7. What purpose do the round ligaments serve and how may they be made to correct the displacement? 8. What is the normal circumference? 9. Name a frequent cause of leucorrhoea. 10. What instruments are needed in curing the uterus and how would you sterilize them?

THERAPEUTICS.

1. Write a prescription for insomnia due to low blood pressure, and give outline of treatment. 2. (a) What is alcohol? (b) Give your idea of its value as a hypnotic. 3. Mention the various forms of malaria and outline of treatment. 4. What are alteratives and what are the ones most frequently used? 5. Apomorphia. Name official preparation; method obtaining it and for what it is given. 6. What are antiferriodes and what are most generally used. 7. Mention the uses of cocain. 8. What is the official name? 9. From what source is cocain obtained? How and for what purpose is it principally used? 10. State some of the circumstances necessitating modification of standard dosage. 11. Give Young's rule for arriving at the proper dose for children. 12. Mention some of the changes in the new Pharmacopoeia affecting the strength of certain tinctures and give the strength of all potent tinctures.

OBSTETRICS.

1. What are the abnormalities of menstruation? Give their etiology and treatment. 2. What are the functions of the placenta? 3. Give the obstetric landmarks of the superior and inferior straits. 4. What changes occur in the breast during pregnancy? 5. What are the symptoms of placental prematurity? 6. Differentiate uterine bruit and umbilical souffle. 7. How may the knee be distinguished from the elbow when presenting? 8. Describe the symptoms and give the management of an incomplete abortion. 9. Into what stages is labor divided and when do these stages begin and end? 10. Describe the mechanism of labor in L. O. A. presentation.

CHEMISTRY.

1. Describe the method of generating hydrogen and mention its properties. 2. Give the physical and chemical properties of hydrochloric acid. 3. Describe atmospheric air and give its composition. 4. Name chemical antidote for arsenical poisoning, how prepared and administered. 5. Mention antidotes in mercury poisoning. 6. Also antidotes in poisoning with mineral acids. 7. Describe the properties and manufacture of iodoform. 7. Describe the symptoms of poisoning by atropin. 8. Define (a) chemical mixture, (b) element, (c) molecule, (d) chemical formula. 9. What metal is used in the two series. 10. Give the names of the terms: (a) amorphous, (b) alkali, (c) water of crystallization, (d) amalgam, (e) nascent state.

The Public Service

Army Changes.

Memorandum of changes of stations and dates of medical officers, U. S. Army, week ending January 20:

Harvard, Valery, asst. surgeon-general, Lynch, Charles, asst. surgeon, Barnall, Carl K., asst. surg., appointed members of a board of medical officers of the Army and of the Navy, to consider improvements in the first-aid dressings and uniformity of equipment for the medical service of the two services. The board will meet in Washington, D. C., at such time as shall be designated by the Surgeon-General of the Army.

Clark, John A., asst. surgeon, leave of absence extended thirty days.

Bourke, James, asst. surgeon, relieved from further duty at Fort Sheridan, Ill., and from temporary duty at Medical Supply Depot, New York City, and assigned to duty as transport surgeon on the *Kilauea*.

Kirkpatrick, Thomas J., asst. surgeon, having arrived at San Francisco, Cal., will proceed to Fort Montrie, S. C., and report for duty.

Raney, Chas. N., asst. surgeon, assigned to duty at General Hospital, Fort Harvard, N. M.

Scott, George H., asst. surgeon, relieved from duty in the Army Transport Service, and ordered to Fort Duchesne, Utah, for duty.

Monroff, Wm. H., asst. surgeon, having arrived at San Francisco, Cal., will proceed to Fort McHenry, Ga., and report for duty.

Pinquard, Joseph, contract surgeon, returned to Fort Leavenworth, Kan., from leave of absence.

Farkman, Wallace E., contract surgeon, granted an extension of leave until he has received orders.

Landerdale, Clarence E., dental surgeon, returned to Fort Sam Houston, Texas, from leave of absence; ordered to Fort Logan H. Davis, Ark., till February 10; Fort Reno, Okla., to March 15; Fort Sill, Okla., to May 1.

White, J. Samuel, contract surgeon, relieved from further duty at Fort Snelling, Minn., and ordered to Governor's Island, N. Y., to accompany First Infantry to Philippine service.

Ferguson, James B., contract surgeon, granted leave of absence for two months.

Woods, Oscar W., contract surgeon, relieved from duty at General Hospital, Fort Bayard, N. M., and ordered home, Roanoke, Va., for amendment of contract.

Carson, Samuel K., contract surgeon, ordered from his home, Riverton, Va., to Governor's Island, N. Y., to accompany the First Infantry thence to Philippine service.

Maer, Fred S., contract surgeon, ordered to duty at Fort Adams, R. I., when relieved from duty with First Infantry.

Eber, Albert H., contract surgeon, ordered from his home Saint Clair, Mich., to Fort D. A. Russell, Wyo., to accompany the Sixth Battalion, Field Artillery thence to Philippine service.

Millikin, John D., dental surgeon, ordered from San Francisco, Cal., to Fort Leavenworth, Kans., for duty.

Hallwood, James B., contract surgeon, arrived at Washington, D. C., and granted leave of absence for two months.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending January 20:

Page, John E., P. A. surgeon, ordered to the *Franklin*, Norfolk, Va. (Orders issued by Commander-in-Chief of Asiatic Fleet.)

Maer, Fred S., medical inspector, detached from the *Wisconsin* and ordered to the *Ohio*.

Barber, G. H., surgeon, detached from the *Ohio* and ordered to the *Wisconsin*.

Thompson, J. C., surgeon, detached from the *Lacton* and ordered to the *Cincinnati*.

Bucher, W. H., surgeon, detached from the *Cincinnati* and ordered to the *Lacton*.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending January 17:

Williams, L. L., surgeon, directed to proceed to Wilmington, N. C., for the purpose of making an inspection of the station.

Stimpson, W. G., P. A. surgeon, granted leave of absence for one month from January 15, 1906.

Cofer, L. E., P. A. surgeon, granted leave of absence for twenty days from January 19.

Clark, Tallaferro, P. A. surgeon, directed to proceed from Philadelphia to Easton, Pa., for special temporary duty on completion of which to rejoin his station.

Richardson, T. E., P. A. surgeon, granted leave of absence for seven days from January 12.

King, W. W., P. A. surgeon, relieved from duty at San Juan, P. R., as chief quarantine officer, and directed to proceed to Washington, reporting at the Bureau for orders.

Burk, M. N., P. A. surgeon, granted leave of absence for two months from January 15, on account of sickness.

Thurkhalter, J. T., P. A. surgeon, granted leave of absence for one month from January 24.

Gibson, L. P., acting asst.-surgeon, granted six days' leave of absence from January 16.

Stearns, W. L., pharmacist, granted seven days' leave of absence from January 13, 1906, under the provisions of Paragraph 210 of the Regulations.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended January 19:

SMALLPOX—UNITED STATES.

California: Imperial and vicinity, Jan. 5, 7 cases; San Francisco, Dec. 23-30, 4 cases.

Delaware: Wilmington, Jan. 6-13, 2 cases.

District of Columbia: Washington, Jan. 6-13, 4 cases.

Florida: Jacksonville, Jan. 6-13, 3 cases; Mascott, 1 case; West Palm Beach, 1 case; Oviedo, 1 case; St. Petersburg, 7 cases.

Illinois: Chicago, Jan. 6-13, 1 case.

Indiana: Lafayette, Jan. 1-8, 1 case.

Louisiana: New Orleans, Jan. 6-13, 6 cases.

Maine: Bangor, Jan. 6-13, 5 cases.

Massachusetts: St. Louis, Jan. 6-13, 2 cases.

New York: Buffalo, Jan. 6-13, 1 case; New York, 2 cases.

Ohio: Cincinnati, Jan. 5-12, 2 cases; Dayton, Jan. 6-13, 1 case.

South Carolina: Camden, Jan. 6-13, 1 case.

Washington: Spokane, Dec. 1-31, 2 cases.

Wisconsin: Appleton, Jan. 6-13, 4 cases; La Crosse, 1 case.

SMALLPOX—FOREIGN.

Brazil: Pernambuco, Nov. 15-Dec. 15, 80 deaths; Rio de Janeiro, Dec. 3-10, 1 death.

Chile: Iquique, Dec. 2-9, 20 cases, 6 deaths.

France: Paris, Dec. 23-30, 13 cases.

Gibraltar: Dec. 18-24, 8 cases, 1 death.

Great Britain: Cardiff, Dec. 23-30, 1 case.

India: Bombay, Dec. 12-19, 4 deaths; Karachi, Dec. 10-17, 1 case; Madras, Dec. 9-15, 5 deaths.

Italy: General, Dec. 21-28, 26 cases; Palermo, Dec. 16-23, 2 cases.

Russia: Odessa, Dec. 9-16, 9 cases, 1 death; St. Petersburg, Dec. 3-9, 6 cases.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, Dec. 3-10, 7 cases, 1 death.

Cuba: Habana, Dec. 30-Jan. 16, 2 cases, 2 deaths.

Mexico: Vera Cruz, Dec. 23-30, 1 case, 1 death.

Nicaragua: Managua, Dec. 9-16, 1 death.

CHOLERA—INSULAR.

Philippine Islands: Manila, Nov. 18-Dec. 2, 5 cases, 4 deaths.

CHOLERA—FOREIGN.

India: Madras, Dec. 9-15, 8 deaths.

Russia: Lomza District, Dec. 7-17, 4 cases, 4 deaths; Mazow, 11 cases, 4 deaths; Ostrow, Dec. 1-17, 3 cases.

PLAQUE—INSULAR.

Philippine Islands: Manila, Nov. 18-25, 1 case, 1 death.

PLAQUE—FOREIGN.

Brazil: Pernambuco, Dec. 1-15, 2 deaths; Rio de Janeiro, Dec. 3-10, 7 cases, 6 deaths.

Great Britain: Liverpool, Dec. 22, on S. S. *Oropesa*, from South American ports.

India: General, Nov. 18-Dec. 16, 11,376 cases, 8,801 deaths; Bombay, Dec. 12-19, 8 deaths; Karachi, Dec. 10-17, 6 cases, 6 deaths.

Medical Organization

Indian Territory.

SIXTEENTH DISTRICT MEDICAL SOCIETY.—Physicians of this district, about 20 in number, met at Ada, January 12, and organized a district society on the standard plan. Dr. M. W. Ligon, Ada, was elected temporary chairman, and Dr. Helge Browall, Sulphur, secretary. Permanent organization was then effected, and Dr. James W. Gilbert, Roff, was elected president; Dr. Bedford E. Sullivan, Stonewall, vice-president; Dr. William H. Greer, secretary, and Dr. W. D. Akers, treasurer. The next meeting will be held at Roff, March 1.

Ohio.

HUBON COUNTY MEDICAL SOCIETY.—The regular meeting of this society was held at Chicago, Ohio, December 14. This society has applied for a charter from the Ohio State Medical Association and made up its list of charter members at this meeting.

MILLCREEK VALLEY MEDICAL SOCIETY.—This society has been established with the following officers: President, Dr. Wilson S. Saffin, Carthage; vice-president, Dr. William O. C. Harding, Elmwood Place, and secretary and treasurer, Dr. J. W. Thiel, St. Bernard. The main object of the society is the exposure of dishonest persons among the clientele of the valley who will not pay debts, although able to do so. Lists of these persons will be mailed by the secretary to each member every two weeks, and the constitution provides as follows: "It is understood that no member of this society will furnish professional services to any persons known as a 'dead beat' unless he is paid in advance for his services or has good private reasons for doing so."

MORGAN COUNTY MEDICAL SOCIETY.—Dr. Edmund C. Brush, Zanesville, counselor for the eighth district, met the physicians of Morgan County at McConnelville, January 5, and reorganized the county society on the standard plan. Dr. Leroy S. Holcomb, Pennsville, was elected president, and Dr. J. E. Brown, McConnelville, secretary. This completes the organization of the eighth district.

Hawaii.

HAWAIIAN MEDICAL SOCIETY.—The annual meeting of this society was held at Honolulu, Nov. 20, 1905. The afternoon session was devoted to reading papers and discussions. The following papers were read: "Acquired Race Immunity," Dr. Carl Ramus, U. S. P. H., and M. H. Service; "Purulent Inflammation of the Middle Ear and Mastoid Cells," Dr. William G. Rogers, Honolulu; "Injuries of Bones, Muscles and Ligaments and Their Treatment by Massage and Movement," Dr. Edward Armitage, Wailuku, Maui; "Constipation: Its Cause, Effects and Treatment," Dr. F. Howard Humphris, Honolulu; "Beriberi and Some of Its Clinical Aspects from Personal Observation," Dr. Charles B. Cooper, Honolulu; "Hawaiian Fever and Typhoid Fever," by Drs. Iza, Mori, Uchida and Kuramoto, was read by Dr. Mori, Honolulu. The matter of local quarantine and purity of the water supply of Honolulu was discussed. The following officers were elected: President, Dr. James T. Watson, Honolulu; vice-president, Dr. Edward Armitage, Wailuku, and secretary, Dr. Aribakhi N. Sinehir, Honolulu. In the evening the annual banquet of the society was held, at which a number of guests, including officers of the army, navy and Public Health and Marine-Hospital Service, were present.

What Can the County Society Do?

VII. CONTRACT PRACTICE.

The subject of contract and lodge practice is one of the most difficult of the practical professional problems now being faced by physicians. There is pretty general agreement that certain forms of contract work are permissible. The question is largely one of fees and of regard for the patients of other physicians. In some localities, e. g., mining regions,

certain forms of contract practice seem too firmly established to be eradicated. Here and elsewhere the effort should be to keep these methods of practice at the lowest possible point, and especially to keep out of the country the more debasing forms.

So the whole matter should constitute the program of a meeting, and every endeavor should be made to see that all sides of the problem are properly presented. After full discussion some endeavor should be made, by resolution or otherwise, that will set the local limits to the extension of the practice. Conditions of professional work vary so greatly from county to county and from state to state that it is in such matters as this that the profession realizes the wisdom of that provision in our present form of organization which permits, and, indeed, compels, each county society to settle its own problems in accordance with local needs.

VIII. INSURANCE WORK.

There are various phases of insurance medicine that need discussion in the medical societies. In regard to casualty insurance there should be concerted action among physicians to aid each other in thwarting fraudulent claims. Public sentiment should be so aroused that the locality will become too warm for the occasional renegade physician who shares in malingerling. The fees for casualty work and for life insurance examinations should be discussed and put on an equitable plane. Professional sentiment should be so aroused and cultivated that no decent medical man will dare to make life insurance examinations at \$65 a month for 50 examinations and \$1 each for examinations in excess of 50 monthly. The good life insurance companies pay a straight \$5 fee and physicians know which they are.

The discussion should include reference to the inadequate fees of the fraternal orders which lead physicians to make slovenly and superficial physical examinations and bring discredit on medicine, both in the eyes of the laity and of insurance executives. The county society may well endeavor to create a sentiment among its members favoring thoroughness in insurance work, for which good fees shall be asked. So long as insurance work is carelessly done by any large number the fees will be low, and so long as physicians pretend that in examining for some lodge they make a thorough examination for \$1 or \$1.50, they must not be surprised at finding it a difficult matter to get all the old-line companies to pay the \$5 fee.

Each county society can well afford to devote some time to this question in the endeavor to raise the standard of professional accomplishment and thereby gain a greater compensation for its members. In different localities, too, other phases of insurance work will suggest themselves as pertinent subjects for discussion.

(To be continued.)

Society Proceedings

BOSTON TUBERCULOSIS EXHIBIT.

Held in Boston, Dec. 28, 1905-Jan. 7, 1906, under the auspices of the Massachusetts State Board of Health and the Boston Association for the Relief and Control of Tuberculosis.

The great success of this illustrated exhibition is shown by the attendance, which reached 24,560, 50 per cent. larger than the New York attendance, which covered more days' time. A large part of the material was loaned by the National Association for the Study and Prevention of Tuberculosis. The active agency in the preparation was the Boston Association for the Relief and Control of Tuberculosis, of which Dr. Edward O. Otis is president and Alexander M. Wilson secretary.

By vote of the Massachusetts Legislature \$2,000 was appropriated for the purpose, and the State Board of Health was designated as the agent of the state in the matter. The co-operation between the two bodies was admirable. Dr. George B. Magrath, for the Board of Health, personally attended to many details. The daily press was most cordial, devoting large space to full reports of the meetings and printing extended advance notices. This adequate information of the public was one of the new features and very valuable.

To secure proper instruction of those attending, 125 guides volunteered. These were medical men and women, many of them well known in the profession. Besides giving an entire evening, just before the opening, in order that they might themselves learn what was to be seen, they came day after day, for a few hours at a time, and carefully explained the different features to the visitors.

The exhibit was made up largely of photographs of various great sanatoria of this country and of Europe, tabulated statistics, models of cottages, tents, rooms and apparatus, drawings and photographs of diseased tissues, samples of the best material, etc. A striking illustration was two rooms, side by side, lighted in the same way. One an example of an average tenement house, the other, the same size, clean, pure and attractive. An exhibit not shown in New York and attracting much popular interest, was a dozen high-power microscopes, under which are shown, by competent enthusiastic experts, the bacilli and the results of their activity in the tissue.

Another valuable feature of this exhibit was a carefully prepared program. In the hall adjoining the exhibition hall, there was a daily lecture and discussion at 3 p. m. and often in the evening a lecture illustrated by lantern slides. Here, on successive days, attempts were made to instruct employers and employes, physicians and nurses, boards of health, philanthropic organizations, institution superintendents, teachers, as well as the alien races, Hebrews and Italians, among whom consumption is now so common. These special exercises were appreciated, for often many hundreds were turned away because every available space had been occupied.

The chairman was in every case one whom the constituents recognized as a leader, e. g., Dr. Arthur T. Cabot, president of the Massachusetts Medical Society; Dr. Samuel H. Durgin, chairman of the Boston Board of Health; George H. Martin, secretary State Board of Education. Gen. Thomas Sherwin, president of New England Telegraph and Telephone Co., and John F. Tobin, president of the Boot and Shoe Makers' Union. The speakers included Talcott Williams, Esq., of Philadelphia, Prof. William T. Councilman, Dr. Vincent Y. Bowditch, Prof. Harold C. Ernst, Dr. Theobald Smith, Dr. E. H. Bradford, Prof. William T. Sedgwick, Prof. Livingston Ferrand and a score of others scarcely less well known.

Many points were emphasized by these speakers again and again. One was the woeful lack of beds for consumptive patients in Boston. New York has 3,216 such beds and Boston only 110. Dr. Durgin showed that of these 110, 60 were borrowed from other institutions, and 50 are in the Long Island Hospital. Moreover, 4,000 tuberculous patients are known to be living in Boston. Still, while in 1856 there were 46 deaths per 10,000 in Boston, in the past year this has been reduced to 20.46 per 10,000 of the population. The board of health proposed a few years ago to build a hospital with 250 beds for \$40,000, but failed to get the money. Later, \$150,000 was appropriated, but was judged insufficient by Mayor Collins and was never expended. Various speakers showed the success of the most inexpensive quarters in tents or shacks, as illustrated in the Wellesley Convalescent Home for Children, and urged that something be done at once. It was claimed that for \$10,000 excellent accommodations of this sort for 150 patients could be provided. Such a method would be following out the examples of many of the best sanatoria, like Riverside at New York, Loomis at Liberty, N. Y., or Sunnyrest at White Haven, Pa.

At the closing meeting, Mayor Fitzgerald assured his hearers that a board of trustees to expend this \$150,000 already appropriated would be appointed at once and a consumption hospital immediately established.

In reply to the letters sent out by the State Board of Health 360 cities and towns reported total accommodations in Massachusetts for consumptives of 971 beds, in both public and private institutions. Only 38 classify tuberculosis among the infectious diseases, which must be reported by physicians, and only 79 have ordinances forbidding expectoration in public places. A sanatorium is planned to be erected at Rutland for persons affected with consumption.

The Boston Instructive District Nursing Association, between Nov. 1, 1904, and Nov. 1, 1905, through its nurses, made 7,014 visits to consumptive homes, took care of 646 patients, of whom 96 were sent to hospitals, and has now 178 patients under its care. Emmanuel Episcopal Church last July started a tuberculosis class of 25 under the direction of Dr. J. H. Pratt. The patients treat themselves, report to him once a week and receive fresh instructions. Three are already cured and ready to go to work.

About one-quarter of the exhibit is to be kept together by Secretary Wilson and sent to various cities of Massachusetts and other New England States.

NORTHWEST MEDICAL SOCIETY OF PHILADELPHIA.

Regular Meeting, held Nov. 6, 1905.

Throat and Nose Diseases Due to Constitutional Causes.

DR. J. L. HARKNESS called attention to the interrelation of constitutional diseases, both as causative factors of and as produced by throat and nose conditions, and emphasized the importance of the specialist in these conditions being also a good general practitioner. He stated that stomach trouble had caused sinus disease. He reported the case of an anemic boy, suffering from indigestion, in whom an examination revealed the presence of a large number of adenoids, which were removed, the removal being followed by cure of the indigestion. He also referred to conditions of the upper respiratory tract, which local applications would relieve only for a short time, because the patient was suffering from rheumatism, which was cured by the administration of the salicylates. He also reported a case of soreness, dryness, dripping of mucus through the nasopharynx, in which an examination revealed mitral incompetency, the treatment of which relieved the respiratory condition. He referred to cases of chorea and epilepsy caused by the nasopharyngeal condition, and the association of varicose veins and hernia with enlarged tonsils, and also the influence of gestation, menstruation and ovarian disease on the nasal condition.

DISCUSSION.

DR. CARL LEE FELT stated that he had never seen any cases which he could certainly say were due to rheumatism, although many cases would be relieved by the salicylates, benzoates and the stimulation of the excretory functions. He cited several cases where the removal of adenoids had been followed by improvement in the general condition of the patient, particularly the digestive symptoms and the blood condition.

DR. RALPH BUTLER stated that one of the most important local conditions due to general causes is vasomotor rhinitis, which is usually relieved by the administration of strychnia or other tonics, while atrophic rhinitis is more amenable to local treatment. Hypertrophy of the lingual tonsils frequently causes stomach trouble, and in all these cases the general condition should be carefully investigated.

DR. WILLIAM KRUSEN emphasized the necessity for considering the correlation of all the organs of the human body in relation to nose and throat conditions, and particularly the importance of rheumatism as a causative factor.

DR. J. THOMPSON SCHELL referred to a severe case of chorea occurring in a boy 9 years of age. He had been under general medical treatment. He was found to have adenoids and enlarged tonsils, which were removed and a circumcision was done. In six weeks he had entirely recovered without any change in the medical treatment. He also referred to another case suffering from epilepsy, in which the removal of the tonsils and adenoids was followed by very marked improvement in the disease.

DR. HUGH P. MCANIFF asked whether it was necessary to remove tonsils that were merely hypertrophied, and whether this had any effect on the nervous system in cases of enuresis, stating that he had seen good result in a patient from the performance of circumcision and tonsillotomy.

DR. H. C. MASLAND referred to a case of enlarged tonsils in which the glands of the neck were supposed to be tubercular. The patient was afterward taken with tubercular meningitis, with fatal result.

DR. A. B. KIRKPATRICK thinks it a good plan to remove the hypertrophied tonsils when it can be done without serious loss to the patient, as by leaving it there is great liability of infection. He referred to the case of a policeman operated on by Dr. D. Braden Kyle six or seven years ago for septal deviation, who prior to the operation had been complaining of pain in the stomach and chest, which after the operation disappeared and has not since returned.

The Subcutaneous Injection of Paraffin for Nasal Deformities.

DR. A. B. KIRKPATRICK exhibited a patient in whom he had injected paraffin for a nasal deformity about sixty hours previously, the condition being due to an operation for straightening the septum and the dissecting out of a dislocated columnar cartilage. This operation had been performed last May, at which time some paraffin was injected, but not sufficient to produce cosmetic effect. He stated that he had never seen any fatal results from this procedure, although he had observed cases in which an excessive amount of paraffin was employed, or in which it was injected in liquid form, and not properly controlled, where the condition of the patient was not improved.

DR. HARLAN exhibited a case of paraffin injection done for saddleback deformity of the nose. The solution injected was a mixture of white vaselin and paraffin with a melting point of 108 degrees, heated to 96 degrees and injected in a semisolid condition.

DR. CARL LEE FELT referred to a plan he saw tried on three patients by making an incision in the skin along the bridge of the nose and putting in a silver plate. Only one of the three cases was a success, the others sloughing out.

Association News

THE SCIENTIFIC EXHIBIT.

Report on the Scientific Exhibit of the American Medical Association for the Session of 1905.

FRANK B. WYNN, A.M., M.D.

Director of the Exhibit.

INDIANAPOLIS.

When Portland was selected as the meeting place in 1905, many persons of excellent judgment seriously questioned the advisability of attempting a Scientific Exhibit at a place so remote from sources of pathologic supply. The dominant sentiment, however, was against any break in the continuity of the good work. This view was prompted by the conviction that even a small exhibit would have a beneficent influence in the Far West, arousing interest in scientific subjects, pathologic and otherwise. The fear entertained by some that the exhibit might fail because of the conditions named above, proved happily not to be well founded. From the extreme East (Massachusetts and the District of Columbia), the Middle States (Illinois and Indiana) and the Far West (California), came those loyal to the cause and regardless of expense, insuring a highly creditable exhibition.

The feature of distinctive interest was the inauguration of a historical department. The auspicious beginning has already secured promises of other medico-historical exhibits for the future of exceptional interest and value. Indeed, the movement bids fair to arouse enthusiasm in a field of medicine too much neglected. A detailed account of the scientific and historical exhibit follows.

I. HISTORICAL DEPARTMENT.

1. INDIANA MEDICAL COLLEGE, THE SCHOOL OF MEDICINE OF PURDUE UNIVERSITY.

FRANK B. WYNN.

An exhibit illustrative of the life and work of Dr. John S. Bobbs, the father of cholecystotomy, inscribed as follows:

Dedicated to the American Medical Association in session at Portland, Oregon, June 11-14, 1905, in memory of Dr. John S. Bobbs of Indianapolis, the founder of the surgery of the gall bladder, by the Medical College of Indiana, the *Indiana Medical Journal* and the Indianapolis and Indiana State Medical Societies, which Dr. Bobbs assisted in organizing, and on behalf of the thousands of patients whose lives have been made happy and prolonged by this beneficent operation.

The more important features of the exhibit were the following:

(a) *Portrait in oil and photographs of Dr. Bobbs.*
(b) *Mrs. Z. Burnsworth of McDordville, Ind., the first person operated on for gallstones.* The operation was done June 13, 1867, on the site of the Commercial Club Building, in Indianapolis, and described by Dr. Bobbs in the *Transactions of the Indiana State Medical Society for 1868*. He was president of the society that year.

Mrs. Burnsworth was brought to the Portland session at the expense of the university, and was formally presented in the exhibit hall at a demonstration on Thursday, July 13, by Dr. L. H. Dunning of Indianapolis. On that occasion she publicly expressed her desire that at death a postmortem examination should be made to determine the exact results which followed the operation. Mrs. Burnsworth is now 68 years of age and in good health.

Dr. Dunning, in presenting Mrs. Burnsworth, spoke as follows:

Mr. Chairman, Ladies and Gentlemen:

The profession of Indiana has taken great pleasure in accepting your chairman's invitation to bring to your exhibit evening the masterpiece of Dr. John S. Bobbs in the performance of the first cholecystectomy in Indiana. It is a great honor to me to be sure one of the first things to catch your eyes has been the portrait of Dr. Bobbs. This portrait was painted during the strength of the middle period of his life, and it at once impresses one with the portrait of a man who possessed unusual intellect, purpose and determination.

Dr. Bobbs was a kindly man, and was always moved by high purposes. He hated shams and hypocrisies. He idealized his work and struggled to realize his ideal. Dr. Bobbs began his life as the foremost surgeon of Indiana. He was a man of great strength of character and hence of wide influence. As evidence of his influence, it may be mentioned that he was in the forefront of all the movements of the State and State Legislature in everything relating to medicine and surgery. He helped to develop the system of administration in the care of the insane, and was one of the first trustees of the Central Insane Hospital. He was influential in organizing the Indiana State Medical Society. He was one of the founders of the Medical College of Indiana, and was its first professor of surgery. In this institution he taught surgery for many years and gave to it his large private library. He also founded and endowed the Bobbs Free Dispensary. He was medical director of the Indiana troops in the Civil War, and served his state efficiently as state senator. He brought to every position he occupied marked ability and faithfulness.

It is not my purpose to eulogize Dr. Bobbs. Another, Dr. P. H. Jamison, has already done this work. It is submitted for your perusal in the reprint, a copy of which you are asked to take with you.

Unquestionably, the greatest work of Dr. Bobbs' life was the performance of the operation of cholecystectomy on Mrs. Burnsworth, the lady who sits in our presence to-day. This lady has endured the long and fatiguing journey from our city to this meeting place. She has traveled with friends, Indiana physicians and their wives, who have had a tender solicitude for her good health and spirits. This good woman has had two crowning days in her life. The first was the one on that mid-June day in 1867, when, in the discharge of his duties to a patient, Dr. Bobbs did, on her person, the first cholecystectomy. The second crowning day is this one, in which, after a long and fatiguing journey, she presents herself before this learned body of men to pay her tribute to the memory and work of her benefactor, Dr. Bobbs. Let the memory of her name be co-existent with that of Bobbs, as is Mrs. Crawford's with that of McDowell and Anarcha with Sims.

The date of Dr. Bobbs' operation on Mrs. Burnsworth was June 13, 1867. It was begun as an exploratory incision, the doctor having told the patient that he was uncertain as to the nature of her tumor, and that he could give no assurance that it could be removed. For a detailed description of the technique of the original operation, you are referred to Dr. Bobbs' original paper, a reprint of which you will find in the one above referred to.

As there has been some misunderstanding relative to some of the procedures in this operation, even by those who have written about it, it may be well to briefly review the steps of the operation. A central incision was made in the median line between the umbilicus and pubes. On entering the abdomen, the omentum was found adherent to the parietal peritoneum. Finding it impossible to deliver the tumor through the prominent part of the enlargement, which was made to pass through it. When the cyst was opened by incision, the fluid contents escaped and along with it a large number of gallstones. The gall bladder was removed, and adhesions, plebs, etc., were looked out of these sacks by the finger. One stone was left, because Dr. Bobbs found no communication between the sack containing it and the cavity of the gall bladder. Further on in his paper, Dr. Bobbs says the stone was removed by the use of the billiard duet. The opening in the gall bladder was closed by a single stitch, the ends of which were cut short and the gall bladder pushed back into the abdominal cavity. The abdominal incision was closed by sutures and adhesive plaster. There was an uneventful recovery, except that there was a small stitch abscess in the abdominal wall.

The greatest interest in this case must be the historical one. Yet it is impossible to understand the importance of the case also attached to it. Where was the unremoved stone located? Dr. Bobbs thought it was in one of the billiard duets. Was it not probably in the cystic duct, into which it had passed, become impacted, exciting inflammation, infection, and finally death? Is inflammation, ulceration, and final closure of both the inlet and outlet of the duct?

What occurred in the interior of the gall bladder after it was emptied of its contents? Dr. Bobbs reported after ten months,

"No appearance of enlargement was observable." Is it not probable that the remaining stone produced considerable irritation, and some constitutional disturbance, for the author states that since the operation she has had intermittent fever at intervals, and impaired digestion, and at such invasions complaints of pain in the region of the enlargement, which became of the stone? What is the condition of the gall bladder and the surrounding tissues to-day? The latter question can not be fully answered without an autopsy.

The result of my examination yesterday leads me to think that the gall bladder and surrounding tissues and organs are massed together by adhesions.

(c) *Documents:* A copy of the "Transactions of the Indiana State Medical Society for 1868," containing the original title and some of the lithotomist of the Gall Bladder"; other addresses and papers; reprints of the *Indiana Medical Journal* and the *Johns Hopkins Bulletin*; letters and testimonials from professional friends.

(d) *Photographs of distinguished professional confrères of Dr. Bobbs in Indianapolis and Indiana as follows:* George W. Mears, Thomas B. Harvey, Joseph Eastman, Theophilus Parvin, D. H. Oliver, W. H. Wishard, I. H. Jamison, J. A. Comins and John G. W. H. Kemper of Muncie.

Mrs. Comins and Avery were present when the operation was performed. It is fitting to close the descriptive consideration of this exhibit by the following just and beautiful tribute to Dr. Bobbs by one who was often his assistant in surgical operations, and perhaps knew him more intimately than any other practitioner of that day:

INDIANAPOLIS, June 28, 1905.

FRANK B. WYNN, M.D.

Dear Doctor:—I am gratified to learn that at the ensuing session of the American Medical Association at Portland you propose to treat of the career of the late John S. Bobbs.

From 1849, when he began the practice in Indianapolis, to his death in 1890, he was the soul of honor and generosity in his demeanor, not only toward the profession, but his neighbors and fellow-citizens. He was incapable of sham, trickery or double dealing in the remotest degree, and still he was self-assertive and yielding in the maintenance of his just rights, but in such a way as rarely to offend. He never administered a placebo. He gave a remedy with a definite purpose or nothing. In his work as a surgeon he was ready to do whatever another had done, and further, he was the initiator where science and common sense indicated the path. He hesitated at no responsibility, however great. I was associated with him in considerable of his work, but can not here enter into details. His scholarship and fidelity in his work with the Rush, Physic, McDowell, Dudley, Gross, Pancoast and other great men who have been an honor to our country. Yours respectfully,

P. H. JAMISON.

2. HISTORICAL EXHIBIT RELATING TO THE EARLY LIFE

OF W. G. T. MORTON.

BY HIS SON, WILLIAM JAMES MORTON, NEW YORK.

This consisted of:

(a) *A portrait of Dr. Morton.*

(b) *Photographic reproduction of his medical diploma.*

(c) *Photographic reproduction of his medical cards while a student in the Harvard Medical School.*

Elaborate amplification of this exhibit is promised for a future session, designed to show the relation of Dr. Morton to the discovery and introduction of ether anesthesia.

II. SCIENTIFIC EXHIBITS.

3. HARVARD UNIVERSITY.

A. *Department of Physiology, Harvard Medical School.*

WILLIAM T. PORTER.

Professor Porter exhibited some of the Harvard physiologic apparatus. This apparatus is distinguished by simplicity in design, sound workmanship and low cost. It is "manufactured" with special tools, and ordinarily not less than one hundred pieces are handled at one time. This collective method, which is that pursued in the best machine shops, combined with the utmost simplicity of design, greatly reduces the cost of the individual apparatus. It enables the physiologist to secure both for research and for instruction an equipment which is at once well made, inexpensive and trustworthy. The enterprise aims to advance the laboratory teaching of physiology. Among the apparatus shown were the following:

Canulus for the blood vessels and the trachea; quantitative circulation scheme; In this latter a can reproducing the intra-ventricular pressure curve causes in the artificial ventricle the changes of pressure actually observed in the dog. With this scheme a number of the physical phenomena of the circulation can be accurately demonstrated. Non-polarizable electrodes made of potter's clay; capillary electrometer for the stage of a microscope; eudiometer; artificial eye in which the course of the rays is made visible; Induction coil; kymograph; leveling table; muscle levers; membrane manometer; micrometer; micrometer; micrometer; apparatus for studying the changes in muscular contraction when the muscle is heated; respiration scheme, with which the variations in pulmonary and pleural transmissions may be studied quantitatively; rheographs; signal magnet; clamps; clamp; electric keys; stopcock, for hemodynamic work; tambour; tuning fork; and work adder, with which the total work done by muscle in lifting a weight may be recorded.

B. Department of Pathology, Harvard Medical School.

HENRY A. CHRISTIAN.

The demonstration of this exhibit was highly appreciated. It comprised:

I. *Biology of the organism of actinomycosis.*
Presented for Dr. J. H. Wright, director of the Pathological Laboratory of the Massachusetts General Hospital.
A series of fifteen lantern slides were demonstrated showing (a) the appearance of the organism of actinomycosis growing in sugar agar with the organisms massed as a definite layer some distance below the surface of the agar and small scattered masses of growth throughout the media; (b) stained sections of the sugar X 1,500, showing the branched forms of the organism; (c) smears from bouillon cultures, showing the organism largely as a bacillary form; (d) portions of colonies of actinomycosis from the pleuralium of a human pleuritic fluid, showing stages in the formation of clubs; (e) the lesions and organism from inoculated guinea-pigs.

II. *Pathologic histology of varicella.*
Presented for Dr. E. E. Tyzzer, assistant in pathology, Harvard University Medical School.

A series of nine enlargements from microphotographs were exhibited and twenty lantern slides demonstrated, showing (a) the appearance of the varicella lesion from its beginning to the stage of advanced healing; (b) the large multinucleated cells (giant cells) so characteristic of the lesion; and (c) the peculiar nuclear and cytoplasmic inclusions in the epithelial and connective tissue cells believed to be degeneration products associated with direct cell division.

III. *Paintings and drawings showing the macroscopic and microscopic appearance of lesions from a case of acute yellow atrophy of the liver in a child of five.*

4. COMMONWEALTH OF MASSACHUSETTS—STATE BOARD OF HEALTH.

CHARLES HARRINGTON, SECRETARY.

This very complete exhibit consisted largely of models, as follows:

- A model of the experiment station at Lawrence.*
This station has been in operation since 1887 for investigations on the purification of water and sewage and allied subjects.
- A model of the Lawrence city filter.*
This filter was constructed in 1893 by the advice and according to the plans of the State Board of Health of Massachusetts. It is 2 1/2 acres in area, and it was the first large sand filter built in America. It has saved many hundred of lives for the city of Lawrence.
- Three small filters to illustrate three types of filters in operation at the experiment station.*
- Three coarse cloth bottles used in the collection of samples for chemical analysis.*
- All forms or sheets used in reporting analyses.*
- Large tables showing the four employed by the State Board of Health in this work, the number of samples examined, both chemically and bacterially, from the beginning of the work up to the end of 1904, and diagrams showing the effect of polluted and pure water on the total death rate and death rate from typhoid fever of two cities in the state.*
- Photographs of laboratories, experiment station and Lawrence filter.*

5. UNITED STATES ARMY MEDICAL MUSEUM.

JAMES CARROLL.

This extraordinary series of 100 brilliant enlargements of bacteria and protozoal parasites was much admired. Dr. Carroll's demonstration made them highly instructive.

- V. leuconatus*, from pure culture, and the same organism showing capsules in the fresh blood of an inoculated rabbit (X 7,000).
- Streptococcus pyogenes* (*longus* and *heeris*), and a streptococcus from a case of suppurative mastitis in the cow (X 7,000).
- Staphylococcus aureus*, *S. pyogenes* (X 7,000).
- M. gonorrhoea* in a pus cell (X 7,000).
- B. prodigiosus*, *B. subtilis*, *B. mesentericus vulgaris*, *B. megatherium* and *Cladobotryella* (X 7,000).
- Bacillus of a clostridium putrefaciens*, *B. diphtheriae*, *Pseudodiphtheria bacillus*, *B. anthracis* stained for spores, *B. anthracis* vegetative forms, *B. typhosus*, *B. coli communis*, *B. tetrades* (Sanarelli), *B. cholerae suis*, *B. influenzae*, bacillus of rabbit antitoxemia, bacillus of swine plague, bacillus of leprosy, *B. aerogenes*, *B. paratyphosus*, *B. paratyphosus*, *B. typhosus* in sputum, *B. tuberculosis* in giant cell in a tubercle of the lung, *B. typhosus*, *B. proteus vulgaris*, *B. tetani* (showing spores) (all X 7,000).

The following bacteria stain for flagella:
Spirillum undula, *B. subtilis* (two), *B. proteus vulgaris*, *B. pyogenus*, *B. typhosus* (two), *B. tetani* (two), *B. cholerae suis* (two), *B. coli communis*, *B. tetrades* (Sanarelli) (all X 7,000).

Actinomyces bovis, in jaw of a cow (X 7,000).
Spirillum of relapsing fever, in the blood of a monkey (two) (X 7,000).

Extra-antennal malarial parasites in stained human blood (four) (X 7,000).

Extra-antennal malarial parasites in fresh human blood (two) (X 7,000).

Tertian malarial parasites in stained human blood (three) (X 7,000).

Quartan malarial parasites in stained human blood (X 7,000).

Leishman-Donovan bodies in smears from human spleen (five) (X 7,000).

Trypanosoma lewisi in stained blood from a white rat (X 7,000).

Pirsonia hominis in fresh human blood (X 1,000).

Pirsonia blumenhans in stained blood of steer, dead of Texas fever (two) (X 7,000).

Amoeba coli in fresh human stool from a case of dysentery. Eight photographs of the same amoeba taken at intervals of a few seconds to show changes of form (X 6,500).

Strongyloides intestinalis in human feces (two) (X 700).

Ova of Uncinaria americana (ten), showing sterile forms and various stages of segmentation (X 3,500).

Ova of Uncinaria americana, showing living embryo in shell (X 3,500).

Uncinaria americana, showing fresh larvae (X 700).

G. PUBLIC HEALTH AND MARINE-HOSPITAL SERVICE.

M. J. ROSENAU,

Director Hygienic Laboratory.

This beautiful and complete exhibit was formally demonstrated by Dr. Rosenau under two headings:

A. *The American Unit for Standardizing Diphtheria Antitoxin.*

This exhibit comprised a demonstration of the unit and the apparatus for making it. The methods of preserving, bottling, distributing and testing the standard toxin and antitoxin were shown, also the special syringes used for inoculating animals with precise amounts devised for this work and the standardized flasks and pipettes.

The demonstration of this exhibit consisted of a concise statement of the good results obtained under the law enacted by Congress, approved July 1, 1902, entitled "An act to regulate the sale of viruses, serums, toxins and analogous products in the District of Columbia, to regulate interstate traffic in said articles, and for other purposes." This law only applies to those persons who engage in interstate traffic in these products and does not reach a few boards of health who make and distribute diphtheria antitoxin within their own state.

In order to engage in interstate traffic in antitoxin it is first necessary to obtain a license, which is issued by the Secretary of the Treasury. The license is issued only after a careful inspection of the establishment by an expert. This inspection consists of a careful scrutiny of the methods, materials and equipment used in the manufacture of the serums in order that a safe and potent product may be assured. In addition to these inspections, which are held once a year, the products of each licensed manufacturer are bought on the open market and examined in the Hygienic Laboratory of the U. S. Public Health and Marine-Hospital Service. Products below the strength claimed for them and those showing impurities are at once reported to the Surgeon General, who takes proper steps to have the matter corrected.

The unit for measuring the strength of antitoxin is based on that established by Ehrlich, and is made in the Hygienic Laboratory in order that there may be a legal American standard of measurement. The antitoxic serum that has been standardized and used as the unit of strength for the measurement of diphtheria antitoxin is kept under strict conditions of light, heat, moisture, etc. From time to time duplicates of the serum will be made to guard against deterioration or accidents to the original.

The standard serum is preserved in small bottles, which were shown. Every two months one of these tubes is opened, tested and distributed to the licensed manufacturers and others who are working in this line. The particular object of this standard is to insure the strength of antitoxic serum sold in the United States by licensed manufacturers.

B. *The Bacteriologic Impurities in Vaccine Virus.*

Petri dishes showing the common bacteriologic impurities in vaccine virus were shown; also agar slants of pure cultures of all the ordinary organisms found in vaccine virus. The publications of the Public Health and Marine-Hospital Service on the bacteriologic impurities found in vaccine virus and on the antisepic and germicidal properties of glycerin, etc., were also exhibited.

The law of July 1, 1902, governing the manufacture of diphtheria antitoxin applies with equal force to the propagation of and interstate traffic in vaccine virus. The contrast between the impurities in vaccine virus before and after the operation of the law was demonstrated. It was shown that before the law became effective an examination of vaccine virus in the Hygienic Laboratory often showed unclean virus, containing many thousands of bacteria per point or per capillary tube, some of them virulent for laboratory animals. Since the licensing, inspection and frequent examination of

the products found on the open market, the bacterial contaminations have shown a gratifying improvement. It is now uncommon to find a vaccine point sold on the open market containing more than a few hundred bacteria, most of them harmless saprophytes.

Several firms did not have the proper equipment and experts capable of producing a safe vaccine virus; these were refused a license and compelled to retire from business.

Foreign manufacturers who sell biologic products in the United States are required to submit to an inspection and license the same as American manufacturers.

7. NORTHWESTERN UNIVERSITY MEDICAL SCHOOL.

WINFIELD S. HALL.

Great credit is due to the Department of Physiology of this institution for the constant and efficient support given the Scientific Exhibit from year to year. The following is a list of the apparatus demonstrated by Dr. Hall at the Portland session:

Physiologic apparatus:
 Kymograph. Vertical writing lever.
 Key, Du Bois Raymond. Chest pantograph.
 Key, simple, with platinum point. Canula, set of six.
 Mercury commutator, Pohl's. Froebard.
 Muscle forep. Tambour, Marey's.
 Crank myograph. Tambour pans.
 Cardiograph, Marey's.
 Tuning fork, electric, 100 vibrations.
 Metronome, with mercury cup after Kronecker.
 Time marker, single, electric after Pfeil.
 Induction coil, Du Bois Raymond, with adjustable interrupter, new form.
 Dynamometer and dynamograph (Smedley's) adjustable grip (Child Study Report, No. 2, Chicago League of Education, page 21).
 Ergograph, Mosso, modified, by Lombard, complete with arm support and weights.
 Frog heart lever with tripod.
 Electrode, non-polarizing, clay point.
 Electrode, non-polarizing, brush point.
 Support, heavy, tripod base, with rod 24 inches long.
 Right angle clamp for use with support.
 Steel styli for use with writing levers.
 Aluminum holder for same and standard clamps, 4 inches.
 Double automatic stimuli key, Relchert's.

8. COOPER MEDICAL COLLEGE.

W. OPHÜLS.

This was a very creditable collection, and constituted the bulk of wet specimens presented at the meeting. It consisted of:

(a) *Kaiserling preparations*—48 in number.
 Eight specimens of endocarditis, of septic origin, illustrating various stages.
 Several specimens of chronic endocarditis, some of which showed complete healing of lesions and an unlooked for regenerative power of the valves.
 One specimen of heart showed a piece of trocar embedded in the septum, the point projecting into the ventricular cavity. It was discovered by accident in an autopsy on a subject dead of chronic tuberculosis of the lungs.
 One specimen of primary carcinoma of the stomach.
 Two specimens of primary malignant cystic tumor of the peritoneum.
 Three specimens of primary adenocarcinoma of the liver with abundant formation of bile in primary tumors and metastases. In two of these there was no cirrhosis.
 One specimen showing chronic gastric ulcer in rabbit following resection of both vagi below the diaphragm.
 Five specimens illustrating the lesions produced by infection with oldium coccidioides (2 in man and 3 in animals).
 One specimen in which there was a plainly visible gray discoloration of the cerebral cortex due to presence of innumerable malarial parasites in a fatal case of malaria.
 (b) *Thirty-six x-ray diapositives* prepared by William Lekkman, as well as a series of x-ray photographs.
 (c) *Dermatologic group* prepared by D. W. Montgomery. They comprised:
 (1) *Collection of photographs of interesting cases.*
 Among these were several illustrating the action of arsenic paste on maligant epithelioma of the skin and some perforating ulcers of the feet in leprosy.
 (2) *Twenty-four diapositives* illustrating the skin lesions, the histologic changes and the parasites in coccidioidal granuloma.

9. SCHOOL OF MEDICINE OF PURDUE UNIVERSITY.

HELENE KNADE.

This exhibit consisted of the following:

(a) *Series of twenty x-ray photographs* illustrative of fractures, gallstones, renal and vesical calculi, prepared by A. M. Cole.
 (b) *Series of dermatologic photographs* (enlarged) prepared by A. W. Braxton.
 (c) *Series of enlarged photographs* illustrating the development of a case of plexiform neurofibroma, of the face and cranium, from infancy to adult life; a gross specimen of the same showing the tortuous, worm like cords; series of water-color drawings by H. Knaide showing the histopathologic changes (report of a case read before Section on Pathology and Physiology by F. B. Wyman).

(c) *Macratome* designed by F. B. Wyman for making section of gross specimens for museum mounts; especially adapted for preparing gelatin mounts in petri dishes and the like.

10. PERSONAL EXHIBIT.

MYRON METZENBAUM, CLEVELAND.

(a) *Series of photographs* showing the clinical value of radium in the treatment of epithelioma and lupus vulgaris.
 (b) *Two prints of a false ulnar joint* from negatives made, respectively, by radium and x-ray exposures. The x-ray was a three-minute exposure, while one week was required for the radium picture. From comparison it is shown that the x-rays have a far greater power of differentiation between bone and connective tissue than has radium. The latter is, therefore, impracticable for making radiographs.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Pneumonia.

In the treatment of pneumonia J. T. Scott, in the *Central States Medical Magazine*, recommends that the patient be kept in bed in a well-ventilated room, at a temperature varying between 65 and 70 F. All the excretions should receive careful attention, unusual care being taken with reference to the sputum. The diet, while light, should be nutritious, and administered at regular intervals. It should consist chiefly of broths and milk, and egg albumin.

In the medicinal treatment, among those preparations which are to be used as cardiac stimulants, he mentions alcohol, aromatic spirits of ammonia, strychnia, digitalis and in some case atropin. In severe cases of circulatory depression he recommends normal salt solution as being of service, given hypodermically or by the bowel. If oxygen is to be of any service in these cases, it must be administered comparatively early, and not omitted until the last stages have been reached.

In those cases in which high temperature is present, associated with disturbance of the nervous system, the cold bath, cold pack or sponging is advised along with the local application of the ice-cap. This procedure is especially of service in restless, irritable and delirious patients. In debilitated subjects, however, tepid baths only should be given. In all cases during the bath friction to the skin should be given, with the previous administration of alcohol. He states further, also, that the baths should not be given too often nor continued for too long a time.

In order to promote the elimination from the skin, pilocarpin may be given, in which instance some cardiac stimulant should be administered in conjunction with it. He regards the cough as a means of exhaustion in certain cases, and states that it should be watched carefully and overcome by sedatives if there be any indications of exhaustion from this condition. For such a cough he recommends heroin as the most valuable preparation, given in doses of 1/12 grain (.005) each, and repeated in four hours, if necessary.

In cases in which the expectoration is too dry and tenacious, Scott recommends the administration of a combination of ammonium chlorid and terpin hydrate. The following combination is also recommended by him for such conditions:

R. Strychnine nitratiss.....	gr. 1/30	102
Guaiaecol carbonatiss.....	gr. i	106

M. Ft. cap. No. i. Sig.: Take one such capsule every four hours.

Acute Prostatitis.

In the treatment of acute prostatitis the patient should be put to bed at once, according to H. M. Christian, in *American Medicine*, and a saline laxative administered once daily. Opium or belladonna suppositories should be used by the bowel two or three times a day, and salol and urotropin (hexamethylenamin) given by the mouth as often. All local urethral treatment should be abandoned, and rectal irrigations should be employed two or three times a day. Irrigations with very hot

water are recommended as giving the greatest relief to the patient. These irrigations can be given easily by means of the ordinary fountain syringe. The patient should be instructed to retain the hot water as long as possible before allowing it to pass out. This procedure of filling the rectum with hot water should be repeated twice at each treatment. The fountain syringe is especially spoken of by the author as being used with much less risk in producing damage to the gland. After a week or ten days, when the acute inflammatory symptoms have begun to subside, and the tenderness of the prostate has decreased by rectal palpation, Christian recommends gentle massage of the gland with the index finger, in order to hasten resolution. This form of treatment must be very gently applied at first in order to avoid the danger of setting up an epididymitis as a complication, which might occur with a too vigorous massage. In the technic of this procedure the patient should be instructed first to empty the bladder. The anterior urethra is then washed out with a solution of silver nitrate, 1 to 8,000, and the bladder subsequently filled with the same solution. While holding the silver solution in the bladder the patient should be instructed to lean over a chair or a table while the physician strips each lobe of the prostate lightly with the index finger about five times. The patient is then instructed to empty the bladder again. In this way the posterior urethra is thoroughly irrigated, the distended follicles of the gland are emptied, and the contents washed out from the urethra along with the irrigating fluid. This treatment should be repeated twice a week for one month or six weeks, at the end of which time resolution will have taken place in the greater percentage of cases.

There is danger, however, of chronic prostatitis developing, requiring a much longer period of treatment before relief can take place.

In addition to the foregoing treatment the author recommends inserting suppositories containing 10 minims (.65) of ichthylol into the rectum at bedtime, as a procedure of great value in promoting resolution. As there is no specific remedy in such conditions, the indications for the internal medication must depend on the condition of the patient under treatment. In the acute parenchymatous prostatitis the suffering of the patient is much greater than in the follicular form, and in such cases Christian recommends that a constant stream of water be passed into the rectum through a tube which has a double flow in order that a constant flow of cold water may come directly against the prostate. This plan of treatment can be pursued almost indefinitely, arranging the temperature to suit the individual case, using the water as cold as can be well tolerated. When the symptoms, such as rigor, hectic fever, and fluctuation on palpation, occur, surgical intervention is necessary.

Intratracheal Medication of Tuberculosis.

The following combination is recommended by the *Journal des Praticiens* in the treatment of tuberculosis by the intratracheal method:

R. Olei eucalypti	
Olei thymi, āā.....	m. lxxv
Olei cinamomi.....	m. iii
Olei olivæ (sterile).....	3iij
Iodoformi.....	gr. lxxv

M. Ft. mistura. Sig.: Forty-five minims to be injected into the trachea once or twice daily.

Dermatitis Venenata.

Dr. E. S. McKee, in *Cincinnati Lancet-Clinic*, states that having been poisoned by poison oak or poison ivy twice, and having suffered severely, he feels that he knows many times more about the trouble than he possibly could have known had he not had this experience. His first attack, contracted at the big trees at Santa Cruz in 1897, was much relieved by bathing in the water of the soda springs at Mount Shasta, and permanent relief was experienced from a plunge and a swim in the hot lake at Mammoth Hot Springs, Yellowstone Park. The water of this hot lake is impregnated with silicate of magnesia. The second attack was contracted in the suburbs of Cincinnati in 1905 and was quite severe, putting both eyes out of use and extending over the whole body, lasting with

nervous symptoms for three weeks. Weak phenol lotions and salves gave temporary comfort, as did weak lotions of borax. Wrapping the parts with cloths saturated in lotio plumbi et opii proved of more lasting benefit, but gave him a severe cold. Dusting the whole body with rice powder gave pronounced relief for several hours, and was nearly always followed by sleep. Saturated solution of aluminum and lead acetate (Burrows' solution), a tablespoonful in a pint of water, used as a lotion, gave fair relief. In his frantic efforts to get the poison off his hands he found that a thick lather of soap gave temporary relief, and the more ordinary the soap the greater the relief. Alcohol gave relief, but the ordinary strength caused too much burning of the skin. He found the following the most useful remedy in stopping the burning and itching, and in checking the spread of the disease:

R. Alcoholis.....	3ii	53j
Aqua dest.	3iiss	47j
Liq. plumbi subacetatis diluti.....	3ii	60j

Sig.: Apply locally.

This gave relief and allowed sleep for six or eight hours. The greater part of the skin exfoliated and the new skin was exceedingly tender for some time, requiring the protection and nourishing influence of olive oil and lanolin. The extreme nervous symptoms yielded to 2-gram doses of sodium bromid given from three to six hours apart, with the addition of two drops of liquor potass. arsenitis to each dose to prevent acne. Dr. McKee says that if one knows that he has been exposed to poison ivy or poison oak and is susceptible, he should bathe the exposed parts immediately with the dilute alcohol of the United States Pharmacopœia. If he applies the alcohol within two hours he will probably stop the progress of the disease by counteracting the poison.

Solutions for Sprays in Coryza.

A correspondent asks for solutions to be used in steam atomizer.

The use of steam inhalations through the nose for the treatment of acute coryza will not afford relief.

The following combinations are recommended by some laryngologists for use locally in an atomizer that will spray oil.

As a stimulant to the mucous membranes:

R. Thymol.....	gr. 1/3	402
Olei caryophylli.....	m. iii	120
Liquid petrolati.....	3i	30j

M. Sig.: To be used in the atomizer as a spray in the nares two or three times a day. Or:

As an antiseptic the following combination is recommended:

R. Acidi carbolici	
Menthol, āā.....	gr. i
Olei gaultheriæ.....	m. i
Liquid petrolati.....	3i

M. Sig.: As a spray three or four times a day.

As a sedative the following:

R. Menthol.....	gr. i	406
Cocaine (alkaloid).....	gr. iii	20
Liquid petrolati.....	3i	30j

M. Ft. mistura. Sig.: To be used as a spray two or three times a day.

[The latter combination should not be refilled without the consent of the physician in charge.]

Other combinations which may be used locally as a spray are as follows:

R. Olei cassiæ.....	m. ii	12
Menthol.....	gr. 1/4	4015
Liquid petrolati.....	3i	30j

M. Sig.: Locally as a spray. Or:

R. Olei caryophylli.....	m. viii	150
Terbenti.....	m. x	65
Liquid petrolati.....	3i	30j

M. Sig.: As a spray.

Internally a combination similar to the following is recommended:

R. Ext. hyoscyami.....	gr. vi	4
Ext. nucis vomicæ.....	gr. iv	2
Camplophoræ monobromatæ.....	gr. xl	2460

M. Ft. capsula No. xii. Sig.: One capsule four times a day.

Medicolegal

Medical Experts on Matters of Common Knowledge.

The Supreme Court of Nebraska holds, in *Turley vs. State*, that matters of common observation, and matters on which jurymen are as capable of forming an opinion as are physicians and surgeons, are not matters for expert medical testimony. But it is not necessarily reversible error to allow a witness to testify to a truism with which all intelligent men are presumed to be acquainted, nor is it in all cases reversible error to allow a witness, over objection, to testify to a proposition of law, or a fact of science or nature which is a matter of common knowledge. Thus the court takes it that the proposition that a human body, when suddenly deprived of all self-control, will fall in the direction of the momentum of the body is a truism with which all intelligent men must be presumed to be acquainted, so that an answer of a medical witness to that effect could not be prejudicial, although the question calling for it could not be properly regarded as a medical question.

Recoverable Expenses in Injury Cases.

The Supreme Court of Illinois says, in *Chicago City Railway Co. vs. Henry*, a personal injury case brought by the latter party, that one who has been injured by the wrongful act of another may recover all reasonable expenses which he has incurred for physician's or surgeon's fees, medicines, and nursing rendered necessary in endeavoring to be cured of his injuries. He must exercise reasonable care to effect a cure and mitigate the effect of the wrongful act and is entitled to recover all legitimate expenses incurred for that purpose, and, if it is proved that further expenses for a surgical operation or medical treatment or attendance will necessarily be required, the jury may take that fact into account. But the court holds that a question as to what a man in the plaintiff's station in life would have to have to be properly operated on by a competent surgeon for hernia, which was said to be \$250, was improper and the evidence incompetent in any view of the case, it not being a case where the surgical operation must be performed, but one where the plaintiff could have it performed or not, as he saw fit, while there was no evidence tending to show that an operation was contemplated.

Previous Physical Condition in Injury Cases.

The Court of Civil Appeals of Texas says that it was contended, in the personal injury case of *Green vs. Houston Electric Co.*, that the plaintiff, having alleged, in substance, that she was, prior to the accident complained of, a sound, healthy and active woman, and that her injuries were entirely produced by the accident, and having supported the allegations of her petition by her testimony, and there being testimony tending to show that she was, in fact, physically weak and unsound before the accident, she was not entitled to recover damages for such injuries produced by the accident as only aggravated a previously diseased or unsound physical condition. But this court can not give its assent to a rule which, in its logical application, would put on a plaintiff the danger of being turned out of court if he should not state in his petition every physical weakness or ailment which might be aggravated in its effect by an injury wrongfully inflicted on him. The court can not find that the doctrine referred to has ever been approved elsewhere; and, while it has not been able to find any case denying it, it thinks that it is at least persuasive that in a multitude of cases examined it appears that persons have been held entitled to recover damages for aggravation of a previously diseased physical condition where the allegations of the petition made no reference to such condition.

No Implied Obligation to Reimburse State for Care.

The Supreme Court of Iowa holds, in the case of *State vs. Colligan*, that, in the absence of any statutory provision authorizing recovery by the state as against an insane person confined in the state hospital, no recovery for the necessary expenses of his support can be had. It says that it finds no authority for holding that the state, having established hospitals for the insane, which are largely charities and provided, in the interest of humanity and for the protection of society, that insane persons shall be confined therein, has any common-law right of recovery against those who receive the benefits of

such public charities. The uniform rule seems to be that there is no liability on the part of the person who receives such benefits, or on the part of his relatives, to make compensation, save as such compensation may be expressly required and provided for by statute. No such obligation is to be implied. This has been the uniform holding, also, as to public aid furnished to poor persons.

Nor does the court consider that a recovery against a non-resident, who was committed to the hospital while in the state, was authorized by the first clause of Section 2297 of the Iowa Code, which reads: "The provision herein made for the support of the insane at public charge shall not be construed to release the estates of such persons nor their relatives from liability for their support." It says that it seems to it that this falls far short of being a statutory provision authorizing a recovery by the state in such cases; and, as the other language of the section relates only to the enforcement of liability by the county of the residence of the patient, which has been compelled by the provision of the statute to pay to the state the expense of his maintenance in a hospital or has supported him in a county institution, it is concluded that there is no expression of any legislative intention to create a liability which may be enforced by the state against the patient or his property.

Mortality Tables and Their Use.

The Court of Appeals of Kentucky says, in the *Illinois Central Railroad Co. vs. Houchins*, a personal injury case brought by the latter party, that, when the action is to recover for the death of a person injured, as the measure of recovery is the value of his capacity to earn money, standard tables, showing the ordinary expectancy of life, are held to be competent evidence. Where, as there was in this case, there is proof tending to show that the plaintiff's capacity to earn money is impaired or partially destroyed, the probable expectancy of life is equally competent, for the measure of recovery here is in part compensation for the impairment of his capacity to earn money. If evidence of the ordinary expectation of life may be received where the capacity to earn money is destroyed by death, it is hard to see why such evidence can not be equally received where the capacity to earn money is partially destroyed; for in either case the jury are, in making up their verdict, to be governed by the capacity to earn money which has been destroyed, and whether this is a partial or total destruction is not material.

The Carlisle Tables are based on actual observation in the towns of Northampton and Carlisle, England. The deaths were taken, not from selected lives, but from the population generally. These tables have been very generally admitted by the courts of this country. The field, however, was so narrow that they have never been regarded as satisfactory. It is a matter of common knowledge that the expectancy of life is increasing. The American Table of Mortality has been made out from the combined experience of the life insurance companies of America, and is now regarded as the standard throughout the United States. It is true that it is based on insurable lives or healthy persons. Still, there is no great difference between it and the Carlisle Table. The Wigglesworth Tables were made before 1858. Since then there has been great advance in medical science, and the data on which such tables are calculated as much fuller now than then. The court, as information increases, will use that table which is the best and most reliable.

After maturely reconsidering the subject, this court has reached the conclusion to follow the rule heretofore laid down and to hold that in each case the expectancy of life may be shown, as any other fact, by the best evidence obtainable, and that, as improved tables come into use which are of standard authority, they may be given in evidence, instead of the older tables which they supersede. Such tables show only the probable continuance of life, and not the duration of ability to earn money. They show the probable duration of life of healthy persons who are insurable risks, and the court, when requested, should tell the jury what the table shows, and that it is to be considered by them, in connection with the other proof in the case, for what it may be worth, considering the plaintiff's state of health and circumstances, in determining the probable duration of his capacity to earn money.

1. **Instruction in Sexual Physiology and Hygiene.**—Morrow says that the education of the public is the most valuable of all measures for the prevention of communicable diseases. Instruction in the physiology and hygiene of the sex function should form an essential, integral part of the education of youth. Morrow criticises our present educational system, the policy of which is to launch the young into the world in complete ignorance of everything pertaining to the laws of life reproduction. Morrow says that in seeking this knowledge the youth is but obeying a law of his mental evolution. Since this knowledge can not be obtained from legitimate sources—from parents and instructors—it is gained surreptitiously and usually from depraved sources—dissolute companions or erotic or quackish literature. To be salutary as a safeguard, therefore, this hygienic education should be given in youth, for it is during this period that the foundations of what may be termed the "sexual character" are laid and habits of mind and practices are formed which, in a great measure, determine the future sexual life of the individual.

3. **Cerebellar Tumor.**—The symptoms in the case reported by Chance were those of intracranial tumor of the hind-brain rather than of the more forward portions, and appeared to be those produced by irritation rather than by the destruction of the basilar centers. Although an intense papillitis, which was present, was conclusive of the presence of a tumor, the indefiniteness of the other symptoms hindered the assumption that the tumor occupied the cerebellar region. The chief local symptoms were those of deviation of the optic axes, with disturbances of direct and binocular vision, and facial palsy; yet, after energetic treatment the paresis of the left external rectus muscle, as well as the diplopia and the facial palsy, greatly disappeared, and when the man was placed under strict hospital regimen the general symptoms all ceased, for there were no headaches, emesis, or muscular spasms, until the last course. The gait, station and the knee-jerks were not interfered with until very late in the progress of the malady. There was hyperexcitation of the sexual function almost until the end. The general bodily nutrition was maintained up to the last weeks of the man's life.

4. **Young Stage of American Hookworm.**—Stiles and Goldberger have succeeded in infecting dogs and rabbits with the American hookworm (*Necator americanus*) by placing the second larval stage of this worm on the skin of the back and guarding against any infection through the mouth. The young worms penetrated the skin, and in from eight to twelve days later they were found in the stomach and small intestine. They had undergone a third ecdysis and reached the fourth larval stage (with provisional buccal capsule). The authors state that there is at present no evidence that these hookworms would reach maturity in dogs and rabbits, hence the conclusion that dogs and rabbits play any rôle in spreading the disease to man is not justified by any facts known.

5. **Uterectomy After Nephrectomy.**—According to Gallant, subcutaneous lumbar pelviperitoneal implantation is simple, safe and satisfactory. He says that by this means we can avoid the additional risk of immediate uterectomy. We can secure free drainage and maintain an opening through which drugs may be introduced to hasten retrograde changes. On the other

hand, the opening beneath the skin does not prevent primary union; avoids exposure on the skin surface; should mucus or pus accumulate it can not burrow in the retrocolonic space, is easily recognized and let out through a small skin incision and a tube inserted for drainage; the absence of ligature on the ureter prevents deep inflammation, and if the ureter must for any reason be removed subsequently, this can be accomplished without difficulty, from a patient who has had ample time to recuperate from the primary operation. The presence of the drainage tube does not interfere with the patient getting out of bed at an early date after operation (in his case the tenth day), nor the exercise of her usual home duties. The drainage tube must be kept in place as long as the discharge continues, and should it close and secretion accumulate, the skin can be incised, and the drain reinserted until atrophy of the ureter is accomplished.

9. **Treatment of Postpartum Hemorrhage.**—Broadhead outlines his treatment of this condition as follows: As soon as the uterus has been emptied, ergot should be given by mouth, or, if the hemorrhage is alarming, by hypodermic injection, and massage of the uterus should be kept up vigorously. Usually a hot vaginal douche of normal salt or weak lysol solution, given at a temperature of 116 F. will be sufficient to check the bleeding. If not, the douche nozzle is carried up into the uterus and a uterine douche of the same solution at the same temperature is given. Hemorrhage continuing, he gives a hot uterine douche of a 2 per cent. solution of acetic acid. For this purpose he carries in his outfit a four-ounce bottle of the Squibb 80 per cent. acetic acid, two ounces of which added to three quarts of water will make a solution of requisite strength. If acetic acid fails, and there have been very few instances in his experience in which it has failed, the uterus should be tightly tamponed with plain sterile or a 5 per cent. iodoform gauze. If one is unprepared to pack the uterus a piece of ice may be carried up and rubbed about in the cavity of the uterus, a procedure which is occasionally followed by firm uterine contraction.

10. **Pathologic Physiology of Typhoid.**—Barach believes that the evidences of to-day are sufficient to establish the modern idea that typhoid fever is a disease dependent essentially on the bacteremia. He thinks that the Peyer's patches and solitary follicles are not the sources from which typhoid bacilli are sent out into the circulation, but that their marked involvement is due to their peculiar histologic structure or to some physiologic relation that exists between the typhoid bacilli and the lymphoid elements. He also believes that perforation with the ordinary pyogenic infection, staphylococci and streptococci, is so much more dangerous than with the pathogenic infection, because to the latter there is already a partial immunity established, and that the diazo is a reaction to an end product, the result of rapid tissue destruction which is characteristic of all marked cases of typhoid fever, and of those other diseased conditions in which the reaction occurs.

16. **Malaria.**—Of the 120 cases of malaria reported by Chamberlain 24 are recurrences in the same individual. Of these

24 cases at least 4 were proved to be new infections by finding a type of plasmodia different from that demonstrated on the first entry. All these new infections and also 6 of the recurrences (probable relapses) occurred while the patients were on a compulsory course of treatment consisting of 0.5 gm. quinin sulphate in solution three times a week. This treatment had been in effect several weeks in each case when fever occurred. On December 11 the compulsory course was increased to 0.5 gm. four times a week, and since then there has been one relapse and one new infection among the men taking this treatment. Chamberlain is of the opinion that these cases prove that neither 1.5 gm. nor 2 gm. quinin sulphate a week is sufficient in all cases to prevent relapse or new infection. These 120 cases are classified as follows: Quartan intermittents, 3; benign tertians, 55, of which 28 were single infection intermittents, 23 were double infection intermittents (quotidian) and 4 were remittent or continued; malignant infections (estivo-autumnal), 62 cases, of which 24 were tertian intermittents, 16 were quotidian intermittents and 22 were remittents. In these 120 cases plasmodia were found in 113, the failure to find plasmodia in 7 being due to a lack of cover glasses during a portion of August. All those in which plasmodia were not found were typical benign tertian fevers. There was in the series one pernicious case. No cases of malarial cachexia developed. Typical parasites were found in all the quartan intermittent cases. The plasmodia were demonstrated in 48 of the 55 cases diagnosed as benign tertian fever, and in many of the cases of double infection the two crops of parasites were easily demonstrated in the blood. In the 62 cases of the estivo-autumnal infections the plasmodia were found in all. Crescents were found only twice, due to the fact that the patients were received promptly on appearance of first symptoms and were treated with quinin before the usual time necessary for development of crescents had elapsed. There were 24 cases of malignant (estivo-autumnal) tertian fever so classified on clinical grounds. There were 16 cases of malignant (estivo-autumnal) quotidian fevers, and 22 cases of malignant (estivo-autumnal) remittent or continued fevers, 2 having tertian paroxysms, 13 quotidian and 7 showing no characteristic periodicity in the febrile reaction. None of these cases continued over a week. Estivo-autumnal plasmodia were demonstrated in all. Nausea and vomiting were marked and annoying symptoms. Out of the 62 cases nausea occurred in 38, and vomiting in 23. These symptoms in most cases were confined to the period of marked febrile reaction. Diarrhea was noted in 7 cases. Abdominal pain, in most cases associated with tenderness on palpation, was recorded in 18 cases. Forty-seven patients complained of headache, and 41 of more or less generalized pain in the back and limbs. Cough was present in 11 cases, and herpes on the lips in 3. Urticaria occurring at the time of paroxysms and ephemeral was noted in 2 cases. No case with infection by two types of plasmodia was detected and no cases resisting quinin and resembling typhoid were observed. The urine was examined in the entire series of cases. Albuminuria was not noted in any case. The treatment employed in these cases consisted of rest in bed, liquid diet and in most cases a cathartic, usually calomel followed by magnesium sulphate, was a routine treatment. When quinin was administered it was given in doses of 0.5 gm. in solution four times daily during the stay in hospital, unless this was unhelpfully prolonged by some pathologic condition other than the malaria. On leaving the hospital each patient was required to take the following course of quinin sulphate treatment: For two weeks 0.5 gm. twice daily, at the end of which 0.5 gm. three times weekly was given for two months. At the end of two months 0.5 gm. daily was given for a week. Quinin was given in solution, except when it caused nausea and vomiting, in which case capsules or tablets were substituted. The action of quinin has been found efficient and prompt in all cases. Arsenic was given in addition to quinin in a few of the recurrent cases.

17. *Perforating Gastric Ulcer*.—The points of interest in the 3 cases reported by Jones are as follows: All cases were perforations of chronic ulcers, the history of ulcer varying from one and one-half to ten years. The perforation occurred

in the midst of a large indurated and thickened area which made it impossible to close the perforation by sutures with any degree of security. In 2 cases the ulcers were located about an inch from the pylorus, directly on the lesser curvature, while in one case it was about three inches from the pylorus and one and one-half inches below the lesser curvature. The time which elapsed between the time of complete perforation and operation was respectively eight hours, seventeen hours and one hour. A gastroenterostomy was done in all three cases; in one case with the Murphy button and in two cases by simple suture. These two patients made a complete recovery. The patient in whom the Murphy button was used died as the result of two more perforations, which Jones believes were caused by the presence of the button. He says that he will never again use the button in such an operation.

20. *Nephroptosis and Nephropexy*.—During the past nineteen years Sturm-dorf saw 112 cases of nephroptosis, and among these 83 patients were operated on, all in the course of the last six years. In this series no mortality and three accidents were encountered; an injury to an abnormally attached, accessory renal pelvis, and two instances of urinary fistula, resulting from superficial parenchymatous lesions produced in the packing of a very adherent friable capsule.
21. *Role of Saline Solution in Pneumonia*.—Taylor says that saline solution, used early, preserves the blood's normal fluidity, renders normal osmosis possible, and gives free sway to the immunizing process. He urges that delay in the use of the salines is just as dangerous as delay in administering antitoxin in a case of diphtheria; and, moreover, that the blood in infections suffers such rapid depletion of saline elements, the effect of which is to impair the efficiency, and finally to arrest the protective functions of, the organism, that this constitutes one of the most active causes of death. The practical recommendation is to begin the internal use of saline solutions, especially those containing sodium chlorid and the other saline constituents of the blood, from the outset in pneumonia and other infectious fevers.
23. *Obstruction of Pylorus*.—Halsey reports seven cases of pyloric obstruction, of which four were benign and three malignant. Six patients were operated on, five of the operations being gastroenterostomies. Of three benign cases in which operation was done only one was suitable for pyloroplasty. Only in one instance of the seven was permanent relief afforded by medical treatment. The author's conclusions are as follows: 1. A history of digestive disturbance extending over several years accompanies the non-malignant conditions; while a perfect euphoria, followed by a few months of increasing difficulty, is associated with the malignant cases. 2. A stomach distended with food contents and in active peristalsis, has an obstruction at the outlet, whether a tumor can be felt or not. 3. An obstruction of the pylorus may be due to a tumor which can be felt in another than the right upper quadrant. 4. The presence of lactic acid and the Oppler-Boas bacilli must not be interpreted to indicate the presence of a cancer; nor, on the other hand, does the finding of free hydrochloric acid and sarcine contraindicate malignant disease. 5. Retention of food in the stomach can cause a suppression of the secretion of hydrochloric acid and permit the formation of lactic acid and the growth of Oppler-Boas bacilli. 6. The selection of treatment should depend on the probable cause, as relief can be obtained in some cases without operation. In selecting the operation, pyloroplasty should have the preference when a choice is possible.
25. *Non-Operative Method of Treating Prostatitis*.—Snow

has treated about forty cases of prostatitis in patients of different ages by means of the static wave current and vacuum tubes. In no case has there been failure to produce some degree of improvement, and in 75 per cent. of the cases so treated there has been complete relief from the symptoms and a cessation of the disposition to relapse. The technique of the method is described and several especial electrodes devised by the author are shown in illustrations. He attributes the effect of the treatment mainly to the mechanical contraction produced and arrives at the following conclusions: 1. When simple congestion is present in the early stages of the affection the relief is prompt. 2. When the gland has been enlarged for a number of years with resulting infiltration and development of vesical irritation and obstruction of the urethral passage, the lesion is capable of being abated and the congestion relieved with the absorption of infiltrated exudates, the hyperplastic tissue only remaining. 3. In the aged, in whom the gland has become greatly enlarged, and is dense and hard from the growth of hyperplastic fibroid tissue, the inflammatory process will be abated, affording a degree of relief to the obstruction commensurate with the site and extent of the inflammatory process. The dilatation of the bladder which has intervened may be greatly relieved and cured in most cases, he states, by the persistent application of the electrical current over the pubis and by an electrode carried high into the rectum and pressed forward against the bladder, together with judicious washing of the bladder and the use of strychnin. The current applied in this manner induces temporarily contraction of the muscular coats, and finally restores sufficient tone to enable the organ completely to empty itself.

26. **New Treatment of Acne.**—Moschowitz has applied Biers' principle of hyperemia to the treatment of acne and reports very good results. The procedure consists in the application of dry cups to the affected region for one-half hour, once or twice a day. The suction must be very slight and the cup is removed and reapplied every one or two minutes. It takes from two to five sessions for each area to effect the desired result. The method does not prevent the appearance of new pustules, although they become less frequent. Eight patients were treated by this method alone with satisfactory improvement.

30. **Antiquity and Fallacy of Animal Extract Therapy.**—McFadden sums up his article as follows:

This theory, as I have shown, is in harmony with the therapeutics of the sixteenth century, which recommended that the extracts from the various organs and glands be administered for diseases of corresponding parts. Between so much faith, and so little, where do we stand? The profession is constantly deluded by those who claim to enlighten us by their carefully prepared statements regarding the clinical and physiologic action of these animal extracts. This makes it more and more incumbent on the intelligent and thinking physician, who is familiar with the history of his profession, ancient, medieval and modern, to limit his prescriptions to the scientific materia medica, of which he is supposed to possess valuable and definite information, and thus great good may finally result from studying this fantastic and superstitious practice, for which in this paper we have found champions, both in ancient and modern therapeutics.

31½. **Operative Treatment of Bladder Tumors.**—Watson proposes to substitute bilateral lumbar nephrotomy and the establishment of renal fistula in cases of bladder tumor for ureteral implantation in connection with bladder resection or total extirpation, and suggests that the bladder operation be done after an interval and not together with the nephrotomies.

36. **New Operation for Relief of Prostatic Ischuria.**—Andrews describes the modification of an operation devised by him in 1902. The operation may be called a prostatolysis or displacement of the organ from between the jaws of the pubic rami to a looser position behind and below. This involves the practical destruction of the urogenital diaphragm to the extent that it no longer forms a transverse musculo-ligamentous septum or floor holding and compressing against the bone, the neck of bladder, and the prostatic urethra. Andrews has devised a large opening made by first pushing up the testes and holding them out of the scrotum with a truss or binder, and then cutting the skin and fat in a curved flap corresponding with the pubic arch. The apex of this flap is the pendulous portion of the penis. When traction is made the opening becomes diamond shaped and shows the following structures from the symphysis backward: (1) A space of fat about one-half inch wide; (2) the ligaments attaching the penis to the pubis, and the prostatico-pubic ligaments between which pass (3) the crura of the corpora spongiosa of each side; (4) a large vein, the dorsal vein of the penis, with two smaller arteries and two nerves. The fibers of the levator ani muscle, embracing the prostate and the inner surface of the obturator internus, come forward in the lateral part of the field, and the deep fascia fills the whole space with a strong covering, which must be cut away in front before one gets inside the pelvic floor. The internal pubic artery, and particularly a large branch to the bulb, must be avoided in doing this. After pushing aside the vessels here encountered and dividing the pubic ligament of the penis, the cutting off of the deep fascia and part of the levator ani allows the membranous urethra and prostate to be pulled into view by traction on the penis. The pubo-prostatic ligaments are now in plain view, and are made tense by traction. They appear to be about 1.5 or a centimeter long, and if they are both divided the prostate will come still further into view. This partial destruction of the pelvic floor is permanent, and is of great value in preventing further compression of the prostatic urethra by the grasp of the levator ani. It also makes the bladder prolapse a little, so that there is no longer a retroprostatic pouch, but the orifice of the urethra becomes the lowest point. Andrews advises cutting the pelvic diaphragm supporting the prostate along both lateral borders. As soon as this is done the whole mass, including prostate and neck of bladder falls freely backward and downward, almost as if it were herniating into a new position. As this is the aim of the operation it need cause no anxiety. After the finger has made a small opening through the urogenital diaphragm its ligamentous and muscular fibers can be held close to this plane. From the operator's standpoint it is much as if he were doing a hysterectomy and had the broad ligament in his grasp. Andrews found that a rapid and bloodless way of making the section is by applying broad ligament forceps, cutting between them and the prostate, and then using homostatic sutures on the stumps. The operation of prostatolysis is complete when the side attachments of the prostate are divided. The wound is closed with only small capillary drains in the corners. The testes easily find their way into the loose dartos again. Little reaction or shock follows this operation, and there is scarcely any danger of injuring bladder, rectum or urethra in doing it.

37. **Prostatic and Periprostatic Abscess.**—Alexander treats all forms of prostatic abscess by opening them into the prostatic urethra through a median perineal incision, whether the

pus is confined within the capsule or has extended outside the capsule, whether it is above the triangular ligament or has extended into the perineum or into the ischioanal fossa. He is convinced that this operation is sound in principle, and that abscesses thus treated heal promptly and with less danger to the patient than by any other method. The technique of the operation is as follows: The patient is placed in the lateral lithotomy position; the membranous urethra is opened on a staff; the prostatic urethra is dilated and explored by the finger; a finger of the other hand is passed into the rectum, and between the two fingers the extent of the abscess cavity can be defined. The abscess is opened by tearing with the finger through the mucous membrane; its cavity is explored, any fibrous bands which traverse it are broken down, its floor is made level with the floor of the urethra, and the opening in the urethral wall is enlarged sufficiently to insure thorough drainage. This is done entirely with the finger; to do it efficiently requires experience; rough and unskillful manipulation may cause severe hemorrhage. A catheter, No. 28 or 30 F., is introduced through the perineal wound into the bladder, and is retained by tapes fastened to a waistband. One or two strips of gauze are passed alongside of the tube to the edge of the abscess cavity, but the latter is not packed. The tube and gauze are removed on the third day, sometimes on the second. The wound is then treated as a perineal section. The patient passes all urine through the urethra before the end of the second week; the perineal wound is healed at the end of the third or fourth week. Some patients require treatment of the posterior urethra for a short time after the complete closure of the perineal wound. In cases of periprostatic abscess in which the pus is above the triangular ligament, the abscess cavity is opened and explored by the finger through the perineal incision; this is possible provided the floor of the membranous urethra is thoroughly cut to the apex of the prostate so as to divide the lower border of the triangular ligament. A large abscess between the rectum and the prostate is to be drained by a strip of gauze passed into the cavity alongside of the perineal tube; this is removed at the end of twenty-four or forty-eight hours. When the abscess has extended into the ischioanal fossa, an additional incision is necessary to drain this space. Perineal abscess beginning in or about Littre's or Cowper's glands or the intrabulbar glands should be similarly treated.

38. Law of Accelerating Risk in Cancer.—According to Andrews, the risk of recurrence in malignant growths increases as the square of the time of growth; or, conversely, the risk of recurrence diminishes in the ratio of the square root of the time after incision. Thus, doubling the time increases the risk of recurrence or metastasis fourfold; tripling the time increases the risk ninefold, etc. The law thus stated, says Andrews, is an admonishment that an early golden period is always given for saving the life of the cancer victim, and imperatively commands action during the brief and precious stage. Andrews maps out a working formula, which, when applied clinically, will determine certain limits beyond which it is useless to operate for a radical extirpation. He calls this the "risk curve." The "risk curve," expressing mathematically the life chances of the patient, is a function of two variable elements—the rate of increase and the total age of the disease. The method of making the curve is described in detail. Andrews has tested his method in a large number of cases, and a few by way of prophecy, and has every faith in its accuracy. By means of this curve he has found it possible to exclude, with fair accuracy, all those cases in which operation could not be performed.

46. Ochsner Treatment of Appendicitis.—Littig contends that the Ochsner plan of treating certain cases of appendicitis can not equal the operative treatment, although, according to

Ochsner, it can so modify a spreading or a septic peritonitis that the mortality will be very small after operation. Littig says that it is here that the non-operating man has sinned. He has applied the Ochsner plan to all cases, whether with spreading infection or not. By his delay he has vastly increased the number of spreading cases. Littig claims that by operating at once, the spreading of septic cases will not be seen; that the Ochsner plan does not apply to more than 0.1 per cent. of all cases during the first twenty-four hours and to not more than 0.2 per cent. during the second twenty-four hours. He believes that operation by a competent surgeon, done as soon as the diagnosis is made, is the only rational treatment for appendicitis.

50. *New and Most Efficacious Method for Removing Facial Tonsils. C. E. DuFour, Washington, D. C.

50. Tonsillotomy.—DuFour believes that the proper method of removing the faucial tonsils, whether enlarged or not, is to enucleate them. In the case of children he gives an anesthetic, inserts a mouth gag, and with proper instruments loosens the tonsil from any attachments to the pillars; then, with a tenaculum or forceps he pulls the tonsil well out of its bed, slips the wire of a snare made for the purpose over it, well down to the base, and then with one stroke enucleates the tonsil. The after treatment consists in spraying the throat with an antiseptic, keeping the patient in the house for several days, and giving soft, nourishing food. The shock of the operation is said to be slight and recovery rapid.

54. Report of the Committee Appointed by the Council of the Medical Society of the County of Kings to Prosecute Illegal Practitioners of Medicine.

51. More Rapid Correction of Scoliosis.—In order to accomplish greater correction of the deformity Truslow substitutes the horizontal for the vertical position when applying the jacket. His method is described in detail. He concludes that systematic physical training is the main therapeutic agent in the correction of lateral curvature of the spine, and that structural changes can not be overcome by muscular efforts alone. Plaster-of-Paris jackets, applied under conditions of progressive longitudinal and lateral traction and frequently renewed, will rapidly overcome muscular contraction. They also may be advantageously employed in suitable cases of moderate severity, but the treatment must be promptly followed by the use of a brace and vigorous physical training.

56. Internal Urethrotomy with Bazy's Urethrotome.—Joly reports the results obtained with this instrument in the treatment of 42 cases. He says that the principal reproach that may be made against the various urethrotomies in general is the impossibility or difficulty of exactly measuring the stricture and consequently the risk that one runs of cutting the healthy portions of the urethra. With Bazy's instrument the seat, length, caliber and number of strictures can be determined exactly. Bazy's urethrotome, contrary to that of Maisonneuve, will only cut the stenosed tissues and will respect the healthy parts. No hemorrhage occurs, although three incisions are made, because fibrous tissue alone is cut. It allows one to introduce a sound of quite large caliber, generally No. 16 Charrière, and in almost all the patients operated on the increase in caliber of the urethra obtained has been quite sufficient without any danger of recurrence.

58. The Stomach of Pulmonary Tuberculosis.—Of the 150 cases considered by Levison, 113 were males and 37 were females. In 32 cases (21.3 per cent.) there was a history of gastric trouble at some time or another, previous to the appearance of the pulmonary affection. Twenty-seven of these patients had gastric symptoms after the pulmonary condition appeared. In 112 of the cases (74.6 per cent.) some form of stomach trouble was present at some stage of the disease. Thus in 85 cases the gastric symptoms followed the pulmonary one. This, says Levison, shows that pulmonary tuberculosis markedly predisposes toward gastric trouble. Vomiting was the symptom in 78 cases. In most of these cases it was the direct result of nausea, after eating. In a number of instances, however, it had no relation to food injection. In a few instances the vomiting seemed to have a neurotic origin. Diarrhea was present in 48 cases.

60. New Truss for Umbilical Hernia.—Kelley describes his truss as follows: It is a pad or plate made of any smooth, impervious material, with little buttons or pegs on the back of it to which are buttoned the ends of the adhesive straps. They can be made of any shape and of different sizes, and the number of buttons or pegs is not an essential point. There should be at least two and, if not more than two, they should be placed vertically with reference to the body. The square shape with rounded corners, and about two and one-quarter inches across, with four buttons, is most convenient. A couple of inches of one end of each adhesive strap is folded on itself and this folded again, and once again, so that there are four thicknesses of plaster strengthening the end. Through this a buttonhole a half-inch from the end is cut with a pen-knife. The folded end prevents the plaster from adhering to the skin near the pad. The straps are buttoned on to the pad and adjusted round the body. The straps can be unbuttoned and the pad removed at any time, the skin cleansed and powdered, and the pad washed and replaced with the greatest convenience and without removing the plaster from the skin. All portions of the skin that are to be covered either with pad or plaster should be washed thoroughly and antiseptically, then the face of the plaster passed over the flame of an alcohol lamp before being applied, and then this hard rubber truss pad used; the strapping can be left on for weeks together and the mother or nurse can do the rest.

63. New Operation for Inguinal Hernia.—In Barnhill's operation the skin and superficial fascia are divided from the spine of the pubis slightly beyond the internal abdominal ring. The external oblique aponeurosis is then divided to about the same point, leaving the lower flap of fairly good width. The sac is then carefully separated from the cord, opened to free it of intestine, transixed, ligated high up and excised, when it will retract through the internal ring. If there are varicose veins in the spermatic cord the largest are ligated and excised. The cord being held up out of the way, the transversalis fascia and internal oblique, including the conjoined tendon, are then stitched to the shelving portion of Poupart's ligament, two stitches being placed in the internal oblique muscle above the opening for the passage of the cord to gather up the muscle and fascia, with a view of obliterating the inguinal fossa, care being taken to bring the cord well down to the lower border of the internal oblique, thus giving it considerable obliquity in passing beneath these muscles. Mattress sutures are then passed through the lower flap close to Poupart's ligament—that is, in the lower portion of the outer flap—catching the margin of the internal oblique and its fascia and the lower margin of the upper or internal flap. Three such mattress sutures are placed in the upper part of the incision over the muscle and cord, the other four being passed beneath the cord.

A small incision, sufficient to make an opening large enough for the passage of the cord, is made in each flap; in the upper one at a point a half-inch below that at which the cord passes out through the internal oblique, and the one in the lower flap at the junction of its lower and middle third. The mattress sutures are then tied and the cord passed through the opening in the upper flap. The lower flap is then carried upward over the cord and stitched to the upper flap above the cord, except the lower third, which is passed beneath the cord and stitched in like manner. Both layers of the superficial fascia are then approximated and the wound closed with a subcuticular silk-worm-gut suture.

65. The Kidneys and the Tongue in Yellow Fever.—Dupiquier says that the tongue of the yellow fever patient is red and raw looking, having a glazed surface studded with enlarged papillae; it resembles the so-called strawberry tongue of severe scarlatinal toxemia. He has observed this tongue on the fourth day in yellow fever, and has observed that it is of grave prognostic importance. He depends on this sign of the tongue as an index of a severe yellow fever toxemia, which will eventually either tell on the kidneys or on the nervous system to the extent of annihilation.

1. Tonicity of the Heart Muscle.—Mackenzie says that in considering the causes of dilatation of the chambers of the heart one can not fail to be struck with the inadequacy of the explanation usually given for this condition. That neither the difficulty opposed to a chamber during its emptying nor the distending force during its diastole is the cause of the dilatation, becomes evident when the conditions observed in certain hearts are carefully studied. The wall of the left ventricle may be so thinned that it bursts in its efforts to overcome the aortic pressure, and yet the walls show no signs of dilatation.

On the other hand, dilatation of the left ventricle may occur even when the diastolic force filling the ventricle is greatly diminished, as in cases of pure mitral stenosis. As the permanent lengthening of the skeletal muscles is due to lack of tone, and as the lengthening of the muscle fibers of the heart is the immediate cause of the dilatation, and, therefore, comparable to the lengthened skeletal muscle, Mackenzie believes that the cause of dilatation will in all likelihood be found to be due to depression in the function of tonicity. He also believes that the causation of the functional murmur at the mitral and tricuspid orifices may be explained as due to a depression of tonicity affecting the muscle fibers forming the auriculo-ventricular ring. He says that anyone who carefully studies the condition of the heart associated with these murmurs can not but be impressed with the fact that they are frequently met in cases that show little or no enlargement of the heart. As, on the other hand, one meets with cases of considerable dilatation without these murmurs, Mackenzie thinks it justifiable to assume that the tonicity of the muscle fibers forming the auriculo-ventricular ring may be differently affected from that of the muscle fibers forming the wall of the ventricle.

3. Peculiar Form of Acromegaly.—Perry's case is of interest because the patient presented merely a local enlargement of the extremities. There was no pain, no nervous irritability, no headache, and no progressive loss of sight and muscular strength. The facial aspect was not characteristic of the disease. There was no enlargement of the thyroid gland. The patient, aged 20, gave a history of having fallen from a tree in his early youth, fracturing the frontal bone. Perry thinks that this fracture may have had some bearing on the local condition either by reflexly damaging the pituitary body or by causing some obscure changes in its growth.

7. Ethics of a Prescription.—Batchelor suggests that in order to protect physicians professionally and commercially, and their patients medically, and to conduce to the fulfillment of the ethical requirements of a prescription, each prescription should be headed by the patient's name and address, and that the prescription should be signed by the writer with his ordinary signature, instead of, as now, merely by initials in such hieroglyphic form that it is only decipherable by himself. The prescriber's address should be given, and it should be stated for how long or for what quantity the prescription is to be made up, and that it should only be available for such time and quantity, and for the person for whom it is written, and that after the prescription has fulfilled the instructions of the writer it shall be dead.

8. Pneumothorax.—McKie reports a case of pneumothorax involving the entire left side and accompanied by no symptoms other than an initial pain. The onset was sudden, without previous manifestation of disease or ill-health. The patient recovered completely.

 14 Case of Melena Neonatorum; Recovery. E. F. Heap.

10. Medical Treatment of Uterine Fibroids.—Wilson states that although uterine fibroids are extremely common, only a small proportion of them give rise to symptoms. In 30 per cent. of those that do the consequences are so serious as to demand operative treatment. Of the other 70 per cent., some with no active symptoms merely require watching, while the others call, in addition, for medical treatment, under which heading may be included minor surgical and other local means. Medical treatment may be direct or symptomatic. The direct or absorptive treatment does not promise much advantage, especially if one bears in mind the many sources of fallacy that interfere with a correct appreciation of the results of treatment. Symptomatic treatment is successful in many cases in tilting the patient over a crisis and in obviating the necessity for operation. Bleeding is most often successfully

treated by rest, ergot, and the intrauterine application of iodine. Pain requires treatment adapted to its cause; alcohol or morphin should only be administered in temporary and exceptional circumstances. The general condition of the patient, and especially the state of general nutrition and the cardiac and renal functions, should be carefully watched. Finally, operation should be recommended when bleeding gives rise to anemia and does not yield to ordinary treatment; when pain is severe and obstinate; when pressure symptoms, especially retention of urine, occur; when the tumor is rapidly increasing in size; and generally when there is evidence that the health of the patient is becoming impaired, and that such impairment appears to be referable to the uterine fibroid.

11. Hemorrhagic Pancreatitis.—Munster cites a case which he thinks is of more than passing interest because the patient survived for ten days after the onset of the affection. He ascribes this unusual duration to the fact that four or five times a day saline injections were given alternately in either axilla, varying in quantity from half a pint to a pint.

Dublin Journal of Medical Science.
December.

- 15 Conjunction of Clinical and Pathologic Work in Medicine. J. P. O'Carroll.
- 16 *Case of Melanuria. T. G. Moorhead.

16. Melanuria.—Moorhead cites the case of a woman, aged 30, who was the victim of a typical melanotic sarcoma of the eyeball for eight years. Eventually she began to lose flesh and her abdomen and feet became swollen. On palpation of the abdomen hard nodules of about the size of a walnut could be distinctly felt all over the upper two-thirds of the abdomen and extending downward into the iliac fossa on both sides. On percussion the abdomen was found to be dull over its anterior aspect from the costal margin to below the level of the iliac spines on each side, except for a transverse area of resonance a couple of inches above the level of the umbilicus. The blood when tested for melanin gave a negative result, and no melanotic granules were present. The quantity of urine passed in twenty-four hours never exceeded twenty ounces in volume. When first passed it was of a deep amber or slightly reddish tinge, but after standing for a few hours it became darker in color, and ultimately almost black. It usually contained a deposit of urates of a deep brownish tinge. A slight trace of albumin was present, but no blood. At the autopsy it was found that the lungs were studded over the surface with a few small melanotic growths. The heart was normal, except for one small tumor, situated in the anterior wall of the left ventricle. The liver was enormous, weighing thirteen and a quarter pounds, and extending right down over both iliac fossae. Its whole substance was infiltrated with black tumors, varying in size from that of a pea to that of a Tangerine orange. Many of them projected on the surface, and constituted the nodules felt by palpation through the abdominal wall. The liver substance between the masses was microscopically normal. The transverse colon lay in front of the liver in the position of the transverse area of resonance above alluded to. The stomach and intestines were normal, except for the fact that the small intestine was only 14 feet in length, and presented valvula conniventes right down to the ileocecal valve. The peritoneum did not contain any actual melanotic nodules, but in many places it was of a diffuse black color. The spleen contained two small nodules, and was normal in size. The kidneys, slightly fibroid, also contained a few scattered nodules, as did the suprarenal capsules. Both these last named structures were unusually large. The pancreas and abdominal lymph glands were normal. Two large ovarian cysts were present, floated up by ascitic fluid above the brim of the pelvis, their wall being constituted by dense black melanotic tissue, about one-fourth of an inch in thickness. The fluid contained within them was of a dirty brown color, but did not give the melanin reaction.

18. Surveillance of Drinking Waters.—Dienert's article shows that the electric conductivity of a water is a good test for changes in it. He is convinced that the drinking water is not the sole means of the spread of typhoid fever, affirming that to date science has no authority for seeking an aseptic water for drinking purposes. Study of the electric conductivity and quantitative determination of the colon bacilli supplement each other and reveal changes in the water. A sudden increase in the amount of colon bacilli suggests the necessity for extra caution.

20. Saline Injections in Prophylaxis and Treatment of Typhoid and Cholera.—The experimental experiences related show that saline injections—either into the peritoneum or under the skin—contribute to the development in the organism, and especially in the peritoneum, of a leucocytosis and phagocytosis which oppose the development of the virus and sometimes destroy it completely when injected into the peritoneum. The saline injections prolonged the lives of the animals and enabled some to survive. After preliminary injections the animals were sometimes able to stand two and three times the fatal dose of the virus.

23. Intestinal Origin of Pulmonary Tuberculosis.—Calmette announces as the conclusions of his research that, in the immense majority of cases tuberculosis of the lungs is acquired by ingestion of bacillus-laden dust or other substances, not by inhalation. It is due to the entrance of virulent tubercle bacilli by way of the digestive tract, the same as glanders in the horse (in case of direct subcutaneous inoculation), is always the result of absorption of the glanders virus by the intestine. He does not agree with von Behring that tuberculosis in the adult is the result of the tardy evolution of intestinal infection contracted during infancy. His extensive research with young and adult goats has demonstrated that the older animals contract tuberculosis by way of the intestine more readily than do the young kids. The kids are also better protected than adults by their glandular apparatus to prevent the spread of the tuberculosis to other organs, especially to the lungs. An important conclusion from his research is the necessity for teaching consumptives not to swallow sputum. In the adult, bacilli make their way from the digestive tract into the lymphatic circulation in the mesentery without injuring the intestinal walls and without meeting with any effectual resistance on the part of the mesenteric glands. It is consequently evident that persons with bacilli in their sputa, who swallow the sputa, are constantly reinfecting themselves. These successive reinfections, he states, produce new eruptions of tuberculosis in the still intact parts of the lungs. It is necessary to supervise patients to determine the moment when they begin to expectorate bacilli, and to teach them never to swallow their sputum. These individuals should also carefully rinse the mouth with boiled or filtered water before each meal, and, if possible, after each expectoration. Bacilliferous dust is dangerous when swallowed.

24. **Origin of Pulmonary Lesions in Tuberculosis.**—Vallée is chief of the veterinary college at Alfort. He comments on the fact that in all species of animals the lung is the chosen tissue on which the tubercle bacillus settles by choice. In 43,000 tuberculous animals the lungs were found affected in 75 per cent. of all the localized cases, and in 100 per cent. of the general cases, while the liver was intact in 17 per cent. His experimental studies have also shown that ingestion of tubercle bacilli is the surest and quickest way to induce tubercularization of the glands connected with the lung. Also that the germs can pass from the digestive tract to the lungs or bronchial glands without leaving a trace of their passage in the intestinal mucosa or mesenteric glands or in any lymphatic vessel. He urges experimenting with young chimpanzees by feeding them with milk from tuberculous cows, in order to estimate the danger of hematogenic tuberculous infection of the air passages and connected glands.

25. **Paralysis After Pasteur Treatment of Hydrophobia.**—Remlinger has found 40 instances on record in 107,712 cases of treatment of hydrophobia in which paralysis followed the Pasteur injections. The paralysis finally subsided in all but 2 cases. Patients taking Pasteur treatment should be warned against getting chilled, as this seemed to be a factor in the paralysis in several instances. Extreme lassitude and weakness in the legs should suggest impending paralysis, and treatment should be suspended until these symptoms disappear.

26. **Phagocytosis in Test-tube.**—Löhlein found that phagocytosis proceeded normally even when the leucocytes (guinea-pigs) had been rinsed entirely free of all extraneous matter and were placed in test-tubes apart from all organic humors. Phagocytosis seems to be, therefore, an act of the cell, independent of the active principles contained in the organic humors. There are certain species of microbes (certain races of streptococci and of colon bacilli) which resist phagocytosis in this way. The results observed with them in the test-tubes parallel at every point the findings with these germs in the clinic.

28. **Infection of Monkeys with Syphilis and Effectual Preventive Treatment.**—In this fourth memoir Metchnikoff and Roux describe their latest experiments, carried on by the aid of the large prizes awarded to them in the last year or so. Of all the monkeys used in the tests the chimpanzees proved the most valuable for the purpose; the syphilis induced in them bore the closest resemblance to human syphilis, while there was no exception to the susceptibility of the animals. The lesions in the smaller monkeys are less characteristic, but these cheaper animals may serve for studying the attenuation of the virus and for research on prophylaxis and therapeutics. It is significant that Metchnikoff found the *Spirochaete pallida* in 23 out of 31 monkeys bearing syphilitic lesions. It might have been found in more of the monkeys, perhaps, if more sections had been stained. In regard to serum treatment, preventive or curative, the experiences related show that more powerful serums than those obtainable at present will be needed for positive results in this line. In preventing the development of syphilis after inoculation of the animals, various expedients were tried, heating the part to destroy the virus, washing with sublimate, and rubbing a mercurial salve into the part. None proved effectual except the latter, but with a salve containing 10 parts of calomel to 20 parts of lanolin they were able to prevent the development of infection after inoculation of the animal with syphilitic virus an hour before. Five monkeys thus treated with the calomel salve failed to show any signs of syphilitic infection after they had been inoculated with the virus which produced the characteristic lesions in the controls. Metchnikoff and Roux, therefore, consider it established that local treatment of parts contaminated with syphilitic virus will prevent the development of the infection. The next question is to determine the length of time in which this local treatment will prove effectual. They inoculated the tip of the ear of a macaque with virus from a chancre on the penis of a syphilitic. Twenty-four hours later they cut away the part of the ear which had been inoculated. No signs of syphilis developed, and when the animal was

inoculated again in the eyebrows sixty days later, it developed typical syphilis. They regard this experience as demonstrating that the syphilitic virus had remained localized at the point of injection for the twenty-four hours. Two other animals in the same test died before definite results could be determined.

31 and 32. **Formic Aldehyd in Smoke.**—Trillat presents evidence to show that the amount of formic aldehyd generated in the smoke of burning sugar, molasses, damp straw, etc., is sufficient thoroughly to sterilize objects in prolonged contact. Smoke from these substances should be regarded as a gaseous disinfecting agent and utilized in practice. The aldehyd is formed in all kinds of incomplete combustion. This throws a new light on the practice of disinfection with smoke, which was in current use in the days of Hippocrates and prevailed until supplanted by chemical disinfection.

36. **Forensic Test for Origin of Blood Spots.**—Neisser and Sachs describe a simplification of the biologic test for blood which is so delicate that it reveals the human origin of even 1 in 1,000,000 e.e. of blood serum. It is based on Moresch's announcement of the anticomplement action of prepared serum, which is the result of the interaction of a substance in the prepared serum with another substance in the normal serum of animals of the same species. Even the minutest amounts of the normal serum are sufficient to induce this anticomplement effect. The test was made with 1 e.e. of a 5 per cent. suspension of sheep serum, to which the amboceptor was added in the form of 0.0015 e.e. of serum of a rabbit preliminarily treated with ox blood, the rabbit's serum acting also on sheep's blood. The complement was in the form of 0.05 e.e. of fresh guinea-pig serum. The serum of a rabbit preliminarily treated with human serum was used for the antiserum. The combined action of the amboceptor and complement completely dissolved the blood corpuscles in the sheep's blood. Addition of 0.1 e.e. of serum from a rabbit preliminarily treated with human serum did not check the hemolysis, but no hemolysis occurred when a trace of human serum had been added to the suspension of blood. This arrest of the hemolysis occurs invariably when there is a trace of human serum in the suspension of blood, but hemolysis proceeds undisturbed when prepared serum of other origin is used. This test can be used to supplement the Uhlenhuth biologic test. After noting the precipitation, the fluid is allowed to stand for a time and then the blood plus the amboceptor is added. The presence or absence of hemolysis impresses even a lay observer as the fluid is decidedly red or colorless, according to the hemolysis.

38. **Treatment of Tuberculosis.**—De la Camp reviews the present status of the treatment of tuberculosis, coming to the conclusion that dietetic measures stand in the foreground, none of the serums yet made having won a permanent place in therapeutics, and cinchamic acid not having fulfilled expectations. In hemoptysis, internal administration of 20 gm. of gelatin, kept up for weeks, has proved the best measure in his experience.

42. **Purification of Drinking Water.**—Friedemann describes the various methods of purifying drinking water inogue.

especially the Siemens and Halske plant for ozonizing the water. As the expense of ozonization is not higher than other methods, he thinks that this may be regarded as the best mode of disinfecting drinking water yet at our disposal. In the tests, even as many as 600,000 pathogenic or allied germs to the *e. coli* were completely destroyed during the ozonizing process.

43. Importance of Spinal Analgesia for Diagnosis and Treatment of Affections of the Anus and Rectum.—Neugebauer states that in 560 cases in his experience in which anesthesia was induced by lumbar puncture and injection, 79 were affections of the rectum or anus. He noticed that after spinal analgesia the sphincters relaxed to such an extent that the anus and the region above it were opened wide for visual inspection. This paresis or paralysis of the anesthetized parts is of great assistance in operating in this region. Spinal analgesia is thus an important aid in operations on the rectum or anus. In 3 recent instances he observed the spontaneous retrogression under spinal analgesia of incarcerated inguinal and femoral hernias.

44. Clamp Forceps with Slit to Suture Through.—Graser gives an illustration of his clamp forceps. The long slit in each blade allows the parts to be sutured with a straight needle through the slit, while the clamp is holding the stumps or parts compressed. The part below the clamp can be cut away and the suture conveniently taken through the long slit in the blades. The slit also enables the clamp to take a firmer hold on the parts. He uses similar clamp forceps in operating on the appendix and for provisional hemostasis in operating on the mesentery or broad ligament.

45. Technic of Enterotomy.—Wolf brings out the lowest distended loop and smooths its contents along, applying two clamps above and below. Between them he takes a purse-string suture, forming an oval about 1.5 cm. long. In the center of this oval an incision is made, and a long rubber tube is introduced and pushed in for a few cm. toward the mouth. The clamps are then removed, and the contents of the intestine issue through the tube and pass into a vessel at its end. When the intestine has thus been emptied the tube is slowly withdrawn by an assistant, and the suture thread is drawn tighter and tighter over the tube. It is finally tied as the tip of the tube emerges. A few Lambert sutures are taken over the first suture for better security. Not a trace of intestinal contents escapes to soil anything, and the whole procedure can be aseptic. It is also applicable when it is impossible to bring out the loop. The segment of the intestine can be isolated from the rest with curved clamps.

47. Treatment of Stump of Duodenum.—Brunner has had trouble from the stump of duodenum after resection of cancer of the stomach by Billroth's second method. He has found records of similar trouble in the reports from other clinics, and has consequently altered the technic somewhat. This modification completely avoids the danger of subsequent peritonitis from the stump of the duodenum. His modification is merely transferring the closed stump of the duodenum to an extra-peritoneal position, that is, to the upper angle of the incision

in the abdominal wall, outside the mobilized parietal peritoneum. In 10 cases in which the operation was concluded in this way the results have confirmed its advantages.

49. The Jaboulay Button.—Klabauer relates a misadventure from the use of the Jaboulay button evidently due to defective construction of the individual button. His experience with it has been satisfactory in the few other cases in which he has used it. The button was illustrated in THE JOURNAL, volume xlii, page 1324.

50. Treatment of Stump of Duodenum.—Steinhilber avoids trouble from the stump of the duodenum, after resection of the stomach, by tamponing the suture. Only one death occurred in 5 cases in which the tampon was applied, and the fatal outcome in this case was due to extraneous causes. The stump is left in its natural position and not pulled on as by the technic advocated by Brunner in paragraph just above. In case a fistula develops, Steinhilber claims that it can be easily treated and cured.

53. Vaccination Against Foot and Mouth Disease.—Loeffler relates the successful results of protective vaccination of domestic animals against foot and mouth disease. An effective and inexpensive method is by injecting under the skin .5 c.c. of a very virulent cattle serum mixed with .03 c.c. of fresh virulent lymph. After about twenty-five days .0033 c.c. of the lymph is injected again, and about thirteen days later .01 c.c. of lymph, and again after the same interval .04 c.c. lymph. The only inconvenience is the necessity for four injections. The technic is harmless and the immunity conferred is comparatively durable. This technic is used for vaccinating all the animals when the disease is known to be spreading in a district. When the disease has already invaded a herd, more energetic measures are needed, and for this he uses powerful horse serum for injections into swine and sheep, and cattle serum for injections into cattle, a single large dose of from 3 to 5 c.c. per kilo. Repeated doses of from 15 to 20 c.c. intravenously, every eighth day are preferable in case none of the animals in the herd is already affected.

56. New Tuberculin in Pulmonary Tuberculosis.—Elsässer remarks that very few communications have appeared on the subject of new tuberculin, since Koch first described, four years ago, his experiences with it in treatment of 74 patients. Elsässer has used it in the treatment of 76 patients, and his verdict is that it is liable to prove very effective if administered in time, that is, during the early stages, while the infection is still purely tuberculous and there is no mixed infection. Even if its curative and immunizing action is not

accepted, the physician can administer it calmly for its virtue as a specific remedy against the fever.

57. Treatment of Tuberculosis of the Joints.—Garré reviews the various indications for conservative and operative treatment of tuberculous affections of the different joints. In his own experience, conservative treatment has given the poorest results when the knee joint was involved. He applied it in 100 cases, but in 46, after the total failure of conservative measures, an operation was decided on at last. Although nearly 90 per cent. were mild cases, yet, on the whole, the results were by no means satisfactory. In 185 cases treated surgically, the results were the complete cure of the tuberculous process in 94 per cent., and excellent functional results in 85.5 per cent. In 100 cases of tuberculosis of the foot, 32 of the patients were treated with conservative measures, with good results in only 14; the others all had to be operated on later. He now restricts conservative measures to recent cases, without a fistula, in otherwise healthy young persons; to cases in which one joint only is affected and the tendon sheaths are not involved, or in which there is no destruction of the bone or focus in the bone; and, finally, to patients of advanced years for whom amputation is the only alternative. Resection of the ankle has given excellent results in 80 per cent. of the 60 cases treated by this means. In 13 patients secondary operations were required to complete the cure. His patients were mostly children, and at this age conservative measures are most likely to fail while the results of resection are particularly favorable.

59. Treatment of Otitis Media.—Urbantschitsch concludes his articles with the remark that the general practitioner should pay more attention to these affections. If the ear were examined as systematically as the lungs, heart and other organs, otitis media would be detected in its early stages and prompt treatment would save the patients from the damage liable to follow neglected catarrh of the middle ear. The general health should be regarded in treating a chronic ear affection. Anything wrong in the intestines, uterus or vascular or other systems is liable to have an unfavorable action on the ear. Tonics, treatment of the uric-acid diathesis, of obstruction, etc., with general hygiene, may have a favorable influence on the ear affection. He is impressed with the great value of systematic exercises in hearing and the therapeutic application of electricity.

61. The Hand as an Instrument in Surgery and Obstetrics.—Ahlfeld wishes to have the hand restored to its old place in obstetrics and in surgery, and urges that it can be effectually disinfected for the purpose with hot water and alcohol. The main point is that the surgeon or accoucheur should be particular to cleanse his hands at once whenever they become soiled with infectious material. Gloves, he states, detract from the delicacy of touch, and they become cut or torn in fully half of all operations requiring sharp instruments. The fact of their being cut is all the more dangerous if surgeons and accoucheurs rely on the gloves and neglect to disinfect their hands thoroughly before commencing the operation. He thinks that it is entirely practicable to disinfect the hands of all pus-forming germs. Whether or not other germs may lurk on the hand is of comparatively little moment.

65. Recent Progress in Treatment of Ear Affections.—Bachauer refers especially to Laval's method of regional anesthesia for the outer ear. A 1 per cent. solution of cocaine is injected to anesthetize the nerves innervating the part. The needle is inserted about .5 cm. in front of the tragus, to a depth of 1.5 cm., paralleling the meatus. To prevent injuring the temporomaxillary joint, the patient holds his mouth open. Half the fluid is injected at this point and the remainder between the cartilage of the auricle and the bone of the mastoid process, on a level with the meatus, introducing the needle for about 1 cm. The nerves involved are a branch of the auriculotemporal nerve in front of the ear and, behind, the auricular branch of the vagus. He sprays the skin with ethyl chloride before introducing the needle. The same principle is followed by v. Eiken, but he reaches the

two nerves by introducing the needle in the fissure behind the cartilage of the ear, just below the cartilage forming the floor of the meatus. He reaches the rear nerve from this point and then draws the needle back and works it in again to the front of the ear while the patient opens his mouth wide. He uses a .5 or 1 per cent. solution of cocaine with .6 per cent. salt. Both he and Laval add a little adrenalin to the fluid. This regional anesthesia answers the purpose perfectly for opening furuncles and abscesses or for removal of small tumors, but the anesthesia is restricted to the outer ear. The middle ear is innervated by other nerves, for which v. Eiken proposes a more complicated technic. One of the more recent innovations in treatment is Sondermann's suction treatment with an aspirating apparatus which fits over the entire ear. He applies suction in this way two or three times a day for three minutes at a sitting. It aspirates all the secretions very thoroughly and can be entrusted to the patient. Politzer recommends the use of paraffin to close the defect in the mastoid after an operation. If the antrum has been opened, the paraffin should not be injected until after the opening has been closed by granulations. Excellent results from the use of paraffin in otology have been published by several writers. The latest innovation in treatment is the application of Bier's congestive hyperemia to suppurative ear affections. The congestion was induced by a padded cotton band about 3 cm. wide, hooked around the neck. A number of eyelets allow the constriction to be graduated to the proper point to induce slight swelling and a bluish-red color in the face. The band was applied for twenty-two hours each day, and even after the signs of inflammation had subsided, it was still applied for about eleven hours a day. The treatment is recommended especially for acute cases of otitis media. A free outlet for the secretions must be provided by paracentesis and, if necessary, a small incision should be made in the mastoid. The pain was arrested as soon as the band was applied in the 20 cases reported by Keppler from Bier's clinic. Heine's experience with 19 cases at Lucae's clinic was not so favorable.

66. Celluloid Splint for Fractures of the Jaw.—Speiser gives illustrations of a convenient, simple and transparent splint for fractures of the lower jaw. It is made of celluloid reinforced with a wire around the base of the two teeth on each side of the fracture, and another wire passed over the teeth and splint and under the first wire.

67. Behavior of the Thyroid in Infections and Intoxications.—This article opens the series of works on the thyroid issuing from de Quervain's clinic. Sarbach announces that the acute infectious diseases, especially scarlet fever, are liable to induce pronounced histologic changes in the thyroid, sparing only the connective tissue, but complete restitution in time is the general rule. The changes are essentially the same for the various acute diseases and for alcoholism. Chronic tuberculosis entails proliferation of the connective tissue. No changes in the thyroid were observed with chronic nephritis, uremia or cachexia from cancer. Of the 67 thyroids examined, 25 were from children under 10 and 52 from adults.

69. **Iodin and Phosphorus in the Thyroid.**—Among the results of the research reported is the discovery that the thyroid in persons living in or near regions in which goiter is endemic contained more iodine than those of others elsewhere. Less iodine was found in the gland in youth and in old age than in middle life, and less in men than in women, while the thyroids of males contain more phosphorus. Acute infectious diseases, tuberculosis and alcoholism reduce the proportion of iodine in the gland, as also disturbances in the circulation. In the cachexia of cancer the iodine was found rather increased. Therapeutic administration of iodine, especially in the form of potassium iodid, increases the proportion of iodine found in the thyroid.

70. **Reaction of the Thyroid to Toxic Influences.**—The literature on this subject is reviewed by de Quervain, who emphasizes the distinction that should be made between thyroiditis from the effect of diluted toxins circulating in the blood, and simple thyroiditis from the effect of toxins elaborated in the gland itself. The latter are much more concentrated. His experience has confirmed him more and more in the assumption that there is some connection between the drinking water and goiter. Strumous degeneration of the thyroid gland in dogs is frequent in regions where goiter is endemic.

71. **Intestinal Disturbances After Operations on the Stomach.**—Anschütz remarks that patients are exposed to more kinds of dangers after operations on the stomach than on most of the abdominal organs. There is unusual liability to peritonitis, to pneumonia and to infarcts, to the vicious circle and to torsion of the implanted loop. At the Breslau clinic 6 cases of peptic ulcer have been observed, and within the last year 2 patients succumbed to sudden and fatal diarrhoea at the seventh and tenth day of apparently smooth convalescence. Constipation is the general rule after a laparotomy, but diarrhoea may occur without any known cause. In 7 cases the diarrhoea was observed in from six to ten days after gastroenterostomy for cancer of the pylorus, proving fatal for 4 of the patients. Diarrhoea was scarcely ever observed after gastroenterostomy for benign stenosis of the pylorus, but it almost inevitably occurred when for any reason a loop of intestine lower than from 40 to 50 cm. from the *plica duodenojejunalis* was selected for the anastomosis. In 60 cases of gastroenterostomy above this limit, no intestinal disturbances were observed except once, and they were then slight and transient. On the other hand, he has been able to find in the literature reports of a number of cases in which a loop 40 cm. below the cecal valve or still lower down was used, with resulting severe, sometimes fatal disturbances. In a case in his own experience, after a standard gastroenterostomy, symptoms of volvulus developed and a cancerous nodule was found and removed from the intestine, requiring a second anastomosis 1.2 meter below the *plica*. Diarrhoea developed as anticipated, but it was finally conquered. In a third group of cases the stump of the stomach was united directly with the duodenum and diarrhoea was observed in a few instances. One patient with ulcer recovered as also 2 with cancer, but a third cancer patient succumbed to the effects of the diarrhoea. This patient was a woman of 45, recovering finely from the operation, when diarrhoea appeared on the seventh day. At first it was not regarded as serious, and possibly might have been a little neglected. The evacuations became bloody and mucous, and finally became a constant stream; the clinical picture resembled that of severe dysentery or diphtheria of the intestines. An artificial anus was made to relieve the intestine, but too late; the patient died the same evening. The main cause for such mishaps, he thinks, is that the debilitated condition of such patients induces a predisposition to diarrhoea. It is remarkable, however, that this predisposition to diarrhoea does not manifest itself at first, but only when the patients are well on the road to recovery. He is convinced, for reasons which he enumerates, that the anesthetic has nothing to do with these intestinal disturbances. The main point in treatment is to act promptly and energetically at the first symptoms of diarrhoea. When it is once well established, all treatment is powerless. Since this rule has been

adopted in the clinic, no threatening diarrhoea has developed. When there is an excess of hydrochloric acid he neutralizes it with an alkali; when it is deficient he supplies the normal amount. He also strives to empty the intestines of harmful contents by powerful purgatives, castor oil, calomel or Carlsbad salts, with astringents and possibly subcutaneous nutrient injections of sugar, salt and fat. The first indication of diarrhoea is met by giving 1 gm. (15 grains) bismuth, with an astringent and 10 drops of opium, repeating this dose every one or two hours. If this is not successful, he increases the dose of opium, giving as much as from 80 to 100 drops of the tincture of opium. Some individuals require more than others to put the intestine at rest. If the diarrhoea is checked a little the opium can be dropped and the astringent continued; but at every new fluid passage the attendants are instructed to give from 10 to 20 drops of opium. If there is a possibility that a loop of intestine too low down has been used by mistake, a secondary laparotomy should be done and conditions righted, or a wide enterostomostomy made to enable the contents of the intestines to be mixed with the digestive juices more thoroughly. An artificial anus may prove of service if made in time. It is important also to learn the previous history of these patients before operating on the stomach. If a tendency to diarrhoea exists, the patient should be supervised with exceptional care.

74. **Functional Value of New Capsule After Decapsulation of Kidney.**—Zaaijer has continued his experiment research on the effects of decapsulation of the kidney in rabbits. He found that decapsulation and scarification of the kidney are followed by the formation of a new capsule which ensured better circulation for the organ than is the case with the normal kidney. By the end of from four to six weeks both the arterial and especially the venous anastomoses were more numerous and effectual than in the normal capsule. There is usually more or less adhesion of the capsule observed in patients requiring decapsulation. Cutting these adhesions amounts to about the same as scarification of the organ in the rabbits. He is now engaged in research with decapsulation of the kidney in diseased animals and also in studying the conditions of the circulation in sound and diseased kidneys, from cadavers.

77. **Suture of Lung or Other Soft Tissue.**—Tiegel has been making a study of the best technic for suturing the lung. His experiments were made in the Sauerbruch under-pressure air chamber, and he shows that the suture in the lung must be solid to avoid after hemorrhage, and also air tight to prevent leaking of air with consequent pneumothorax. He applied air pressure to the lung after suturing it and found that very few sutures were able to fulfill these conditions. He finally devised a technic which answers the purpose perfectly, the suture standing a pressure of 40 mm. This was accomplished by running a skewer, made of magnesium, into the tissue, on each side of the wound, and suturing the lips of the wound together, with fine silk, the running suture embracing the skewers. The best results were obtained when the silk was dipped beforehand in a solution of iron chlorid, which aided in promoting coagulation and thus filling up the stitch holes. The same technic is applicable to the liver, spleen, pancreas, gravid uterus and the heart, and also for inflamed or degenerated tissues in the intestine or stomach, and for closing a gaping wound in the peritoneum. He has found the technic fully as satisfactory when suturing the liver after a wedge-shaped excision. Payr's tests of magnesium have demonstrated its harmlessness for the tissues and its rapid absorption when its task is completed. He uses the magnesium skewers to stick into angiomas, and has reported a number of cures by this means.

80. **Scopolamin-Morphin Anesthesia.**—Roith has collected 3,709 cases in which this form of anesthesia was used, and estimates that the number actually has reached 4,000. He discusses the 18 cases in which death occurred, and states that in some of them the anesthetic could not possibly have been responsible for the death. In others exceptionally large doses were given. He has used it in 230 cases, and has been favorably impressed with its superior advantages. He mentions a number of minor points in the technic, and remarks that the sole disadvantage of the method is that the solutions used must be made fresh every time. The Korff and Kimmel techniques are perfectly harmless, he thinks, and any one can be sure of success by following their directions. Mishaps are due to disregard of the results of others' experience. There is no danger in using hyoscin (scopolamin) in small doses, and the small doses are equally as effective as the larger ones. Repeated small doses of from .3 to .6 mg. are preferred by the psychiatrists. He gives 3 mg. of hyoscin plus 1 mg. of morphin an hour and a half before the operation, following this with .4 mg. of hyoscin plus 1 mg. of morphin half an hour before the operation. Early in the morning or the evening before the operation he gives a very small dose of some sedative to very excitable patients. Control tests with atropin-morphin given in 200 cases in the same way, he states, showed the superiority of the scopolamin-morphin technic. He always plugs the ears of the patient with cotton.

82. The "Spleen Point."—Signorelli has found that the sensibility of the skin is altered in certain places whenever there is inflammation or other morbid process in the spleen. In case of acute tumefaction of the spleen or exacerbation of a chronic tumefaction, a zone of cutaneous hyperalgesia, he says, will be found corresponding to the fifth interspace on the left, near the left nipple. This is what he calls the "spleen point"; it may be a little to one side or above or below the nipple. In addition to this zone in front, there is frequently a corresponding zone at the fifth, sixth, seventh or eighth spinous process, and occasionally another in the side, corresponding to the sixth or seventh interspace on the median axillary line. The zones correspond to Head's sixth metameric segment, and throw light on the embryology and physiology of the spleen and aid in differentiating affections of this organ.

83. **Typhoid Bacilli in Urine.**—Maione found typhoid bacilli in the urine in 40 per cent. of his typhoid patients, but very rarely before the eighth day. In some instances, however, the bacilli were found in the urine three days before the agglutination test was positive. The Drigalski-Corradi technic reveals the presence of the bacilli in forty-eight hours.

85. **Raw Kidneys in Nephritis.**—Arrallani describes the particulars of 10 cases of nephritis treated with a maceration of fresh pigs' kidneys, according to Renault's method. (The technic was described in *THE JOURNAL*, page 340, of volume XLII, 1904.) Six of the patients were cured, 2 much improved, and 2 not benefited. The 2 failures occurred in cases of very serious chronic uræmia. The cases mentioned as being much improved were likewise very severe and chronic cases. The patients cured had the acute forms of nephritis with edema. The rapidity of the cure was astonishing in two instances. There can be no doubt, he thinks, that the maceration has a directly beneficial action on the pararenal of the kidneys, promoting diuresis and elimination of chlorids and urea, the

effects of which are soon felt in the improved metabolism. It also acts on the blood pressure, reducing it to normal limits. No unpleasant by-effects were noticed in any of the cases. This treatment can be combined with ordinary measures without harm.

88. **Distension of the Stomach and of the Intestine in Diagnosis of Abdominal Affections.**—Arnone concludes this comprehensive article with a three-column summary of the various diagnostic points which he has been studying. He shows in a number of illustrations the changes in the shape, size and position of the stomach or intestines in case of a tumor in them or in any adjacent organ. The changes are characteristic, and have considerable differential value, especially when the effects of insufflation of the stomach or intestine are compared with normal findings.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE EDINBURGH STEREOSCOPIC ATLAS OF ANATOMY. Prepared under the auspices of the Department of Anatomy of the University of Edinburgh, by Professor J. K. Cunningham, M.D. (Edin., 1861), LL.D. LEPROSY IN THE PHILIPPINES, WITH AN ACCOUNT OF ITS TREATMENT WITH THE X-RAY.*

H. BROOKMAN WILKINSON, M.D.
Physician in charge, San Lazaro Hospitals.
MANILA, P. I.

As is generally known, leprosy is diffusely scattered throughout the entire Philippine archipelago, not being much more abundant in any one locality than in another. The actual number of cases is variously estimated at from 5,000 to 10,000. Whether the disease is increasing or decreasing at the present time can hardly as yet be even surmised, nevertheless we do know that in the neighborhood of Manila, where for several years an attempt has been made to segregate it in this hospital, we are constantly receiving new or previously unreported cases. The new admissions during the past three years since I have been in charge of the hospital, have been variable as to the apparent stage of the disease, but it is extremely rare to find a case in which the disease is limited to so small a localized region of the body, as to indicate recent local infection. On the other hand, a large proportion of new patients admitted to the hospital give an undoubted history of the disease dating back from one to ten years, from which fact I am sure that in practically all cases the disease could have been diagnosed earlier, had the patients been examined by an experienced physician. It is also quite probable that we are surrounded by, and more or less in constant contact with, numerous cases of leprosy in its early stages of development.

It is practically impossible to draw any reliable conclusions as to the exact duration of the disease in any given case on account of the general ignorance of the masses, with reference to its early recognition and differentiation from numerous other skin diseases so common here, as well as to their lack of fear of the disease and their consequent inclination to conceal its presence in order to avoid segregation or confinement. Also the point of inoculation or the source of infection can rarely, if ever, be determined on account of our inability to locate the cases at an early stage of the disease, or to ascertain the approximate time of infection. These difficulties are increased by the customs of the natives which dispose them to frequent change of residence and association, as well as by the fact that anywhere they happen to go they are liable to find one or more sources of infection in the immediate neighborhood.

While from these remarks it can be seen that the exact method by which this disease spreads is very doubt-

ful, still there have been a few facts noted among our cases which throw some light on the subject.

We find that for several years past there has been only one case where a husband and wife have been known to have the disease, and in this case the disease appeared at the same time in both, indicating a common origin rather than a transfer from one to the other.

Of numerous children born in the Philippines of leprous parents (seven in this hospital, three having both parents leprous, but not married), none have been known to suffer leprosy.

I have been able to locate five cases in which a parent and child have both had the disease, but the development occurred toward the end of the child's adolescence, appearing at about the same time in both parent and child, the child developing the disease first in three cases, and the parent first in two cases, thus indicating common origin and not transmission from parent to child.

We have had five families represented by two children; three families represented by three children; and one family represented by five children. In this latter family there were ten children, the other five with both parents remain free from the disease.

From these facts, I am inclined to believe that the disease is rarely, if ever, transmitted from parent to offspring, and is with difficulty transferred directly from one person to another, but there frequently exists a common source of infection to which the members of the same family may be subjected especially during early childhood.

For the purpose of the following comparative observations I have taken the histories of 239 patients, 238 of whom were in the hospital at the time when these statistics were prepared, December, 1904, while the other was admitted soon afterward and is included on account of the subsequent improvement and cure under x-ray treatment. As can be readily understood, many difficulties were encountered in obtaining accurate histories of these cases, the principal of which being the variety of languages spoken, Spanish, Tagalog, Ilocano, Visayan and Bicol being represented, and the sluggish mental condition of many of the patients due to their station in life and their long, hopeless confinement. In this work, as well as in the microscopic examinations of slides and the use of the x-ray apparatus, I have been efficiently assisted by Dr. Rizal Mercado, the house physician, and by Miss R. Mickle, one of our trained nurses, both of whom kindly volunteered their services.

With each case we carefully inquired into the history of the development of the disease, especially with reference to the time when the first symptoms appeared, the time spent in this hospital and the existence of the disease in relatives. Then an examination was made of the present condition of the body, noting the parts involved, the class or variety of the disease, whether hypertrophic, atrophic or mixed, the amount of disfigure-

* Read before the Manila Medical Society, 1905.

ment estimated in per cent. of disability and the percentage of vitality. Ordinarily, vitality and disability would vary inversely one with the other, but disability is here used to mean the disability caused by the maiming action of this particular disease, while vitality is used in its ordinary general sense.

After this procedure, microscopic slides were made of scrapings from the specific lesions and, in all cases found negative by the first slide, three additional slides were more carefully made and examined. If these slides were not positive, for the purpose of classification, we called the case bacteriologically negative, although in most cases we carried the work further for the purpose of reconfirming the negative examination.

In the classification of the varieties of this disease, I have used the terms hypertrophic and atrophic in place of the more ordinarily used terms tubercular or nodular and neurotic or anesthetic, as I find that these latter terms are liable to much confusion as well as being, in

The mixed variety is simply a combination of the other two, usually one form being apparently of much more recent origin than the other.

Of the 239 cases reported, 97 are hypertrophic, 47 atrophic, 92 mixed and 3 undetermined; one of the latter being probably atrophic and two not leprosy at all, but lupus vulgaris. In the entire number of patients the disease has existed to an extent to be recognized for an average period of 8.11 years, and the average period of their residence in this hospital has been 2.55 years. Seventy-seven of the patients have had the disease for 10 or more years, twelve for 20 or more years, one for 31 years and one for 41 years. Seven patients have been in this hospital for 10 or more years, two for 17 years and one for 18 years. Of the forty-seven atrophic cases, I find that the average time during which the patients have been known to have had the disease has been 12.28 years, while the average time in this hospital has been 4 years.

Fig. 1.—Case 9. C. de los S. This photograph was taken Nov. 9, 1904, and shows well-marked hypertrophic leprosy. She has improved slightly under treatment.

Fig. 2.—Case 8. M. M. This photograph was taken Nov. 7, 1904, and shows hypertrophic leprosy before treatment.

fact, misleading. Under the head of hypertrophic cases, we include cases showing tubercles and nodules or mass and plate-like increase of tissue, while under atrophic we include those cases showing scars and glossing of skin, anesthetic patches, wasting away of the fingers and toes, etc.; in other words, when hypertrophy exists we call the variety "hypertrophic," and when atrophy exists we call it "atrophic."

The hypertrophic forms develop most rapidly and are usually diagnosed earlier; they ulcerate freely and promptly and the lepra bacilli are easily found in great abundance in all cases by simply taking a scraping from any of the hypertrophied parts (Fig. 1). The atrophic forms develop more slowly, rarely, if ever, ulcerate; the bacilli are found with difficulty in scrapings and the patients display the greatest variety of deformities, with frequent loss of toes and fingers.

The average estimated disability or deformity for the entire 239 cases is 53 per cent.; twelve patients show no disability; ninety-six show less than 50 per cent. disability; thirty-seven show 50 per cent. disability and ninety-four show more than 50 per cent. disability.

The average vitality of the entire number is estimated at 68 per cent. There are five patients with 100 per cent. vitality, or practically normal; 158 with more than 50 per cent.; fifty-six with 50 per cent.; and twenty with less than 50 per cent. vitality.

On microscopic examination of scrapings from the leprotic lesions, I found 193 positive for the lepra bacilli by the first slide taken and 46 negative. Subsequently I made three slides from each of these 46 negative cases and found 20 of them positive, there remaining 26 permanently negative for lepra bacilli in scrapings from the skin. I have made numerous subsequent

Fig. 3.—Case 8. M. M. This photograph was taken Sept. 23, 1905, and shows marked reduction of leprotic deposits after x-ray treatment.

Fig. 5.—Case 5. D. P. This photograph was taken Jan. 19, 1905, and shows entire disappearance of leprotic deposit, only scar tissue remaining.

Fig. 4.—Case 5. D. P. This photograph was taken Nov. 7, 1904, and shows patient after disappearance of most of the leprotic deposit.

Fig. 6.—Case 12. A. M. This photograph was taken Jan. 19, 1905; x-ray treatment was begun Jan. 9, 1905, and marked improvement has already been noted. This photograph shows x-ray burn on the cheek.

examinations of many of these negative cases and continue to find them negative, but in a few patients who have since died, I have been able to demonstrate the bacilli in nerves which supply the atrophied regions of the body. It is interesting to note that all of these twenty-six permanently negative cases belong to the atrophic variety, except three. One of these three is classed as doubtful, but I am inclined to class it as atrophic, while the other two are probably lupus.

X-RAY TREATMENT.

The treatment of leprosy with x-rays was begun by me in this hospital in January, 1904.

In treating the patients, I have always selected the part of the body which presented the greatest amount of leprotic deposit and usually exposed it to the rays for ten minutes at a distance of from seven to ten inches. The distance and time of exposure were varied somewhat from time to time, and an effort was made to approach as near to the point of burning the skin as possible without actually doing so. In only two cases was the skin actually burned, and it is interesting to note that they are the first two patients herein reported as cured. During treatment, the patient never suffers and can only notice a slight tickling sensation over the area treated as if a slight wind was blowing on the skin. After two or three successive treatments, a blushing of the skin may or may not be noted, and usually a sensation of itching is experienced by the patient. Should superficial burns occur, treatment for the time should be suspended until tissue repair begins. These burns have shown little tendency to progress and have healed readily, leaving little or no scar.

Below will be found a tabulated list of thirteen patients treated during the past year. All these patients have been natives of the Philippines, and are numbered from 1 to 13 for easy reference:

No.	Sex.	Age.	Duration of Disease in Years.	Number of Treatments.	Date of Treatment.	Result.
1	F.	15	9	44	Jan. 31, 1904.	Not improved
2	M.	8	1	13	Jan. 23, 1905. Apr. 25, 1904. Nov. 21, 1904.	Not improved
3	M.	8	5	11	Apr. 23, 1904.	Improved.
4	F.	10	3	12	Apr. 23, 1904. Nov. 21, 1904.	Not improved
5	M.	37	1	14	Apr. 11, 1904.	Cured.
6	F.	12	5	40	Sept. 8, 1904. Feb. 1, 1905.	Improved.
7	F.	14	1	37	Sept. 10, 1904.	Improved.
8	M.	13	1	38	Jan. 27, 1905. Sept. 10, 1904.	Improved.
9	F.	12	7	11	Jan. 23, 1905.	Improved.
10	M.	16	5	12	Jan. 23, 1905. Oct. 27, 1904.	Improved.
11	M.	36	18	15	Jan. 20, 1905. Oct. 27, 1905.	Improved
12	M.	19	2	52	Jan. 17, 1905. Jan. 9, 1905.	Cured.
13	M.	25	2	14	June 7, 1905. May 8, 1905.	Cured.

As will be seen by an examination of the table, three patients have been cured, seven improved and three not improved.

I am unable entirely to explain why Cases 1, 2 and 4 were not improved by the treatment, still in none of these cases did we have a large mass of leprotic tissue to which we could apply the rays. In Case 1 the patient had a few patches scattered over the face and body, and while the individual patches to which the rays were applied improved slightly, the disease apparently continued to progress in other parts of the body. In Cases 2 and 4 the patients had practically no localized patches,

and the treatment was stopped after a short unsuccessful trial.

In Cases 3, 6, 7, 9 and 10 the patients showed definite improvement with considerable decrease in leprotic deposit, the advance of the disease being apparently for the time checked. In Case 10 the patient showed marked decrease of facial hypertrophy, but at the same time a loss of general health, possibly due to an over dosage of necrotic elements.

Cases 8 and 11 were both unusually far advanced and the patients were badly disfigured; they both improved to a marked degree, not only in parts of the body exposed to the x-rays, but in distantly removed parts of the body which the rays did not reach. In Case 11 the man had enlarged and ulcerated ears, lumps on the face and enlarged, thickened and ulcerating hands, with loss of the ends of several fingers. After application of the rays to his hands, where the tissue showed the greatest hypertrophy, not only did his hands decrease in size and the skin clean off, but the ears became smaller, the ulceration healed and the skin of the face became more normal. In Case 8 the patient showed very unusual nodular developments over the face. With treatment, these nodules gradually disappeared to a very marked extent, as seen in Figure 3. The gradual improvement in this case seems to be progressing, if anything, more rapidly at this time. September, 1905, than at any previous time, although treatment has been suspended since January.

CASE 5.—D. M., male, native of medium size, aged 37, was admitted to hospital July 29, 1904. A clinical diagnosis was made of well-developed hypertrophic leprosy. On the day of admission duplicated slides were made from skin scrapings and were sent to the government laboratories; both were reported positive for *lepra bacilli*.

Examination.—On admission the patient appeared fairly well nourished. He talks Spanish unusually well and is much above the average in intelligence. He had been employed in the United States Quartermaster's Department as a laborer. The right side of his face showed marked thickening of the skin and superficial tissues, the entire surface being elevated from about one-half to three-quarters of an inch and of a deep purplish-red color. The thickening of tissues was so great that his right eye was practically closed and the right ear enlarged from two and a half to three times its normal size. On the point of the chin there was a nodular enlargement about the size of a horsechestnut. On the forehead, the left cheek, the chin and the neck were numerous small nodules about the size of a split English pea.

Treatment.—On August 11, x-ray treatment was begun, the application being the rays from a bifocal tube at a distance of ten inches for ten minutes.

Treatment as on August 11 was repeated on August 12, 13, 15, 16, 17, 18 and 23. On examination August 23, I found that the tumefaction of the face was markedly reduced and that the right eye could be more widely opened. Superficial ulceration or burns had appeared on the helix of the right ear and on the eminence of the right cheek, from which ran a seropurulent fluid. Treatment was suspended for the time.

August 31: The superficial burns had somewhat increased in size since last treatment and a tendency to break down was noted in the nodules on the chin and on the side of the neck.

September 4: The burns had dried over and were covered with scabs or crusts. X-ray treatment was resumed.

September 9: There was still a superficial burn about the size of a twenty-five cent piece on the eminence of the right cheek. The ear, chin and neck were better. X-ray treatment was given on September 4, 7 and 8, but had now been discontinued.

September 22: The burns on cheek and chin alone remained and they were nearly well. The face and ear were much reduced in size and all the nodules heretofore noted and also two or three on arms appeared to be gradually disappearing. The large nodule on the chin was much reduced in size.

October 15: The patient had gradually improved. Most of the hypertrophy of face and ear had disappeared, leaving considerable scar tissue. The eye was wide open and the outer canthus was beginning to be drawn outward by scar tissue. The right ear was still somewhat enlarged, especially the lobule. Pus taken from the partly broken down nodule on the chin showed lepra bacilli.

November 7: Photograph taken November 7 (Fig. 4) shows the condition clearly. The right ear, especially its lobule, was still somewhat enlarged. The face showed some inflammatory and much scar tissue. The chin showed some of the small nodules, but the large one had practically disappeared.

December 15: Skin scraped from the cheek showed a few scattered lepra bacilli. Skin and serum taken from healed nodule on chin showed a few scattered, imperfectly stained, apparently beaded and broken-up lepra bacilli. Pus and serum from crust on the right ear showed no lepra bacilli. The patient was rapidly improving so far as his leprotic manifestations are concerned, but his general physical condition was not good and he seemed to be losing in general health.

Jan. 12, 1905: Three days previously a soft, indolent, fluctuating abscess appeared in the right groin just above Poupert's ligament, and, on being opened January 12, discharged about eight ounces of yellow, thick pus. Microscopic examination of this pus showed numerous streptococci, but no lepra bacilli.

January 19: Photograph taken January 19 (Fig. 5) shows plainly the improvement in face and ear.

February 2: Microscopic examination of skin and serum taken from the right cheek showed a very few scattered, headed and apparently broken-up lepra bacilli, but no clumps. Specimens taken from several other parts of the body were negative.

July 1: The appearance of face and ear were normal so far as leprosy is concerned, but there was considerable white scar tissue scattered over this area. No part of the body showed any signs of existing leprosy. Microscopic examination of skin scrapings from different parts of the body, especially right side of face, nose and chin, were all negative. The general physical condition of patient deteriorated rapidly during the past six months and he was suffering from general anasarca and from anemia; he also had albumin in the urine.

July 11: Patient died. The cause of death was general debility following atrophy of liver, anemia and general anasarca.

Autopsy.—Autopsy held by Dr. Maximilian Herzog, pathologist of the government laboratories, the summary of whose autopsy report, with his full microscopic report, follows:

D. P., male, Filipino, 37 years of age. Autopsy held three hours after death showed: Fatty degeneration of myocardium and kidneys, with interstitial nephritis, advanced atrophic cirrhosis of liver, purulent abscess in the anterior abdominal wall just above Poupert's ligament, anemia and edema of brain, general anasarca and general profound necrosis. The serous cavities and soft tissues all contained serous fluid in considerable amounts. There were old pale cicatrices of the right side of the face; the integument in many places was somewhat scaly, but nowhere were there seen formations such as we find in tubercular leprosy.

Microscopic Examination: Tissues were taken for microscopic examination from the following places and organs: Two pieces from the left side of face from the area which appeared somewhat depressed, pale and cicatricial in character, from the ear which formerly had presented a nodular tubercular appearance, from the kidneys, spleen, liver and heart and from several peripheral nerves. These tissues were fixed in Zenker's fluid, subsequently embedded in paraffin, sectioned and stained with hematoxylin-eosin and with Ziehl's carbol-fuchsin and methylene blue.

In the sections from the skin and those from the ear, which latter took in all of the tissues of the concha, the subcutaneous layers showed patches of a subacute, loose, inflammatory infiltration composed of lymphoid cells. In these areas, however, neither epithelioid nor giant cells were found. Likewise lepra bacilli could not be demonstrated. The liver presented

the histologic picture of a well-advanced cirrhosis. The increased interacinous connective tissue was mostly of the fusiform variety with a few small, round lymphoid cells here and there. Lepra bacilli were not demonstrated in the hepatic sections. An examination of the renal, splenic, cardiac and nerve sections likewise failed to show lepra bacilli.

In other words, neither the histologic nor the bacteriologic examination in this case furnished any evidence at all that the patient at the time of his death was suffering from leprosy, either cutaneous or internal. (Signed) Herzog.

CASE 12.—A. M., male, Filipino, aged 19, was admitted to the hospital Dec. 12, 1904. A clinical diagnosis of hypertrophic leprosy was made. The duration of the disease was said to be about two years.

Examination.—On admission the patient appeared well nourished and in good general health. He had numerous dark, reddish, elevated leprotic patches on the face, arms, legs, and more especially on the back. The individual patches appeared congested and puffed out and seemed to be about one-eighth of an inch higher than the surrounding skin. The fingers of both hands were drawn to a half-shut position, and there was slight contraction of the muscles of the legs so that his walking was impaired. On December 14, microscopic examination of skin scrapings from cheek showed lepra bacilli present.

Course of Disease.—On Jan. 9, 1905, x-ray treatment was begun; applications were made to the lesions on the right side of the face at a distance of eight inches for ten minutes.

The x-ray was applied on January 9, 10, 11 and 12. On January 12 a small blister was noted on the cheek about the center of the point of exposure.

January 19: A photograph was taken (Fig. 6); a blister on the cheek had gradually enlarged to the size of thumb nail and then scabbed over. X-ray treatment had been transferred to a larger blotch on the back which is oval in shape, about three and a half inches by two and a half inches in size, abruptly elevated one-eighth of an inch above surrounding parts and deep red in color. A portion of the spot treated on the face showed some fading of color and reduction of elevation. One spot on forehead not treated directly has been reduced from a very perceptible elevation.

January 31: This patient had been treated seven times up to date, viz.: January 9, 10, 11, 12, 19, 20, 21 and 23, and showed marked reduction of the cutaneous manifestations of leprosy, not only at the points treated, but to just as great an extent on parts of the body most distant from the points of application.

July 1: There had been a wonderful improvement in all of the leprotic manifestations of this patient during the past five months, during which time he had had seventeen applications of the x-ray, making a total of twenty-four applications. All the elevated, dark-colored spots on the face and body had disappeared and were replaced by slightly depressed, light-colored, scar-tissue-like spots, which appeared slightly striated and drawn as if by newly formed connective tissue.

The deformity of the fingers had disappeared from all except the little fingers and had markedly decreased in them. The defect of the muscles of legs had entirely disappeared and the patient walked naturally.

July 21: Three microscopic examinations were made, one from cheek and two from back; all were found negative.

July 25: Three microscopic examinations were made; one from the face, one from a scraping of the mucous membrane of the nose and one from the back; all were found negative.

July 27: Microscopic examinations were made of tissue from arms and cheek; all were negative.

August 3: Three microscopic examinations were made; all were negative. The patient was considered cured.

August 8: Four microscopic slides were made by Dr. M. Herzog and examined at the government laboratories; all were found negative.

August 16: Three slides made on this date and three on August 14 were all found negative.

September 30: The patient remained apparently well, and frequent microscopic slides made recently all proved negative for lepra bacilli (Fig. 7).

CASE 13.—B. M., male, Filipino, aged 25, was admitted to

hospital Feb. 21, 1905. Duration of the disease was about two years. The clinical diagnosis was atrophic and hypertrophic leprosy.

Examination.—On admission the patient appeared to be in fairly good general health and a little above the average in intelligence. He had a slightly elevated, dark leprotic patch on the upper lip, covering in the region of the mustache and extending slightly beyond, a patch the size of a silver twenty-five cent piece about the center of the left cheek, and one the same size on the anterior surface of right elbow. The posterior surface of the right elbow showed some anesthesia and the skin was glossy. There was beginning atrophy of the right little finger nail, and this finger was contracted to an angle of about thirty degrees, the next finger was bent to an angle of fifteen degrees and this entire area showed slight anesthesia. A microscopic examination of skin scrapings from the patch on upper lip showed lepra bacilli.

Course of the Disease.—On May 8, 1905, x-ray treatment was begun on the upper lip.

July 1: X-ray treatment had been given fourteen times; May 8, 9, 12, 13, 17, 19, 22, 24, 26, 29, 31, and on June 2, 5

doubtful acid-fast objects which appeared to be broken-up and degenerated lepra bacilli. Slides taken on August 11 and 16 have all been negative.

GENERAL REMARKS.

As may be seen from the above, there is absolutely no doubt that at least one patient (Case 5) with genuine leprosy has been cured by the application of x-rays. This case I have reported in considerable detail with every practicable form of confirmatory evidence in order to establish the fact as a basis for future work along this line. As may be noted, this case was clinically diagnosed not only by myself, but by numerous other physicians, the diagnosis was twice confirmed, by microscopic examinations made at the government laboratories, and on three successive occasions confirmed by myself microscopically. The treatment and gradual improvement was watched

Fig. 7.—Case 12. A. M. This photograph was taken Sept. 23, 1905, and shows scar tissue where leprotic deposit formerly existed and entire disappearance of lepra bacilli.

and 9. The patient appeared practically well on July 1, only a slight discoloration remaining on the upper lip. Lepra bacilli could not be found there.

August 1: It was impossible definitely to outline the patch which formerly existed on the upper lip; not only had the infiltration entirely disappeared, but the discoloration practically all had been absorbed. It was difficult to locate the spot that formerly existed on the cheek, and the other manifestations had likewise decreased (Fig. 8).

On several occasions I have been unable to find lepra bacilli, and on account of the entire disappearance of deposits I have included this patient among those cured, although I am continuing treatment and am not satisfied of the permanency of the cure for two reasons: First, because the disappearance of symptoms has been too recent, and second, because in one of a number of slides taken August 3, from this patient I found several

Fig. 8.—Case 13. B. M. This photograph was taken Sept. 14, 1905, and shows absence of leprotic patch over upper lip and left cheek and disappearance of lepra bacilli after x-ray treatment. No photograph was taken before treatment.

by quite a number of physicians in Manila. Then we have the cure represented in a photograph and also confirmed by myself several times microscopically and finally confirmed both macroscopically and microscopically at the autopsy by the government laboratories. The only part of the record with which I am not satisfied is the photographic, as I should like to have had a photograph showing his condition on admission. The other two patients reported as cured are now in apparent good physical condition, and I hope that their future history may demonstrate the permanency of the cure.

HOW DOES THE X-RAY TREATMENT OPERATE?

I am inclined to believe that when a local lesion of leprosy is treated with x-ray, the organisms there localized are killed and their bodies absorbed by the system

thereby producing an immunity against the living organisms. This as may be seen would be practically analogous with the immunization of individuals against bubonic plague by injecting into them killed cultures of plague organisms. In our case we simply grow the culture of lepra bacilli in the human body as a culture medium and then kill them by the use of the x-rays.

In support of this theory, I cite the following facts:

First. The treatment of one leprous spot on a patient produces improvement in spots at a distance from the one actually treated.

Second. The cure in the distant spots seems to progress parallel to and to be just as complete as in the one treated.

Third. The best results seem to be obtained only when treatment is pushed to the point of killing or beginning to kill the tissues, which would also probably be to the point of killing the organisms.

Fig. 9.—Case 10. P. P. This photograph was taken Nov. 7, 1904, and shows a case of well-developed hypertrophic leprosy.

Fig. 10.—Case 10. P. P. This photograph was taken Sept. 15, 1905, and shows reduction of leprotic deposit with loss of physical health after x-ray treatment.

Fourth. Cases in which there are massive localized leprous deposits, as in Case 5, are most rapidly improved. As in these cases, we have an abundant culture on which to operate and thereby produce immunity more rapidly.

Fifth. In diffuse general involvement of slight degree or atrophic character where there are only a few scattered organisms we have had little success.

Sixth. In two well-advanced cases in which the amount of new leprotic tissue was excessively great, the improvement was marked and rapid, but followed by loss of general health and rapid physical decline (Figs 9 and 10). This may be an over dosage, so to speak.

LIMITATIONS AND DIFFICULTIES ENCOUNTERED IN THE USE OF THE X-RAY MACHINE.

Being so far away from the source of supplies, we have had much trouble in keeping a satisfactory supply of tubes and in having repairs made to our x-ray machine.

I have not as yet been able to find any one in or near Manila who really understands all the parts of an x-ray machine so that defects could be located and repaired without delay. The repair work has fallen mostly on myself, and while I am able to take the machine apart and frequently successfully to repair it, still it is often a process of try and see and often try again. The tubes frequently burn out or wear out, their internal resistance becoming too high and not infrequently the sparking power of the machine falls from ten inches to even three or four inches, thus rendering it useless. One time the batteries are at fault, next and most frequently the interrupter is at fault, then the Leyden apparatus is blamed, and finally the internal resistance of the tubes becomes too great. So I must admit that to use an x-ray machine for from twenty minutes to one hour a day over a period of several months and to get active effective results from it is not an easy matter.

In conclusion, I wish to express my gratitude to Major E. C. Carter, U. S. Army, our former Commissioner of Public Health, for the interest which he took in procuring the necessary apparatus and for the encouragement which he gave me during the progress of this work.

Tuberculosis.—Ch. Sangmann, in the reports of the sanatorium of Velefford for 1904 (*Archives Générales de Méd.*), declares that Flügge's theory that tuberculosis is disseminated by coughing is not supported by his observations. Out of 182 physicians who have served in the sanatorium from 1846 to 1882, all before the recognition of the infectious nature of consumption, only nine ever suffered from tuberculosis. From further data collected by Sangmann, including the figures from 69 sanatoria with three or four physicians and 66 physicians connected with laryngologic clinics, he has not been able to find a single case of infection acquired by a physician in the exercise of his profession.

MOSQUITO WORK IN RELATION TO YELLOW FEVER ON THE Isthmus of PANAMA.*

W. C. GORGAS, M.D.

Colonel and Assistant Surgeon-General of the United States Army and Chief Sanitary Officer, Canal Zone.

ANCON, CANAL ZONE.

I shall confine myself more particularly to the question of yellow fever and malarial fever. While we have to deal with all tropical diseases on the Isthmus and to establish a health department such as any community of the same size in temperate zones would be obliged to have, these two diseases, yellow fever and malaria, were the great ones that had caused the principal mortality in the two great works before undertaken down there, namely, the building of the railroad and the attempted construction of the canal by the French. The conditions were much the same as had confronted us in Havana, with the exception that in Cuba we had for two months in the year cool weather during which mosquitoes bred scarcely at all; in Panama there is no difference of season except that between the wet and dry season, and mosquitoes breed as readily in January as in July. Another difference is that at Panama we have a country district of 50 miles in extent to guard against malaria troubles; in Havana we merely had the suburbs of the city to attend to in this respect.

During the French occupation the heavy mortality among their European employés had been a potent factor in the failure of the canal work. It is difficult for us to get statistics that represent exactly the losses under the French. Their work was done under the contract system, the canal line having been divided up into seventeen divisions and let to seventeen different contractors. These contractors were charged a dollar a day for every sick man to be taken care of in the hospitals of the French company. The tendency would be, therefore, when a man became sick for his employer to discharge him so that he would not have to bear the expense of his care. The French company were building a canal through the Columbian territory, just as the Pennsylvania Railroad built its track through Pennsylvania; they had no police control whatever of the territory along the canal. They had no means of telling how many of these employés of the contractors died along the line. All that they could know was that so many reported for work each day; what became of the others they had no means of telling. At their large hospital, Ancon, they kept very accurate statistics, and the number of deaths that occurred there can be safely quoted as entirely correct, but it leaves a very great limit of uncertainty as to what portion were treated in hospital and what proportion died along the line. The English consul, who was down there during the period of construction, is inclined to think that more deaths of employés occurred out of the hospital than in it, and he had very good opportunities for judging. Nine-tenths of the laborers were Jamaican negroes, English subjects, and looked to the English consul for care and protection. The consul tells me that he personally knows of a great many being found dead along the roadside while endeavoring to find their way to him in the City of Panama, and some even dying in his office. On the other hand, the old French superintendent of hospital, Dr. La Croisade, who is still with us, thinks that the hospital statistics represent most of the deaths.

It seems to me, both from what I can find out as common opinion on the Isthmus, and what would seem to me to be human nature under the circumstances, that it is a fair conclusion that the French statistics represent not more than half the mortality that actually occurred. And in quoting these statistics I will ask that this be borne in mind.

The United States Government took over the canal property in May, 1904, but for various reasons there was considerable delay in getting sanitary work fully started, and the authority for doing sanitary work in the towns of Colon and Panama was not granted till toward the latter part of February, 1905. We then built up much the same organization here that we had developed in Havana. All cases of yellow fever were required to be reported to the American health authorities, and in addition to this, all cases of fever of any kind occurring in an American were also required to be reported. It was a considerable advantage to us in Panama that the equipment of our hospital allowed us to give very much better nursing, care and medical attention to all patients than could be obtained elsewhere on the Isthmus. For this reason, Americans generally reported to the hospital when they had fever of any kind, and we usually got cases of yellow fever within the first day or two of the disease. This resulted favorably to the patient as well as to the sanitary authorities; while the general mortality was about 25 per cent. of all cases, the mortality of the Americans treated in our hospitals was not more than 10 per cent.

As soon as we took possession of the hospital, we had two wards thoroughly screened and equipped for keeping out mosquitoes, just as had been our wards in Havana. The suspected patient, when brought up, was placed in one of these wards. It is interesting to see what entire confidence all of our people soon acquired in the mosquito theory of the transmission of this disease. Ancon Hospital is beautifully situated on the side of the Ancon Mountain overlooking the City of Panama and the Pacific Ocean. It is pleasantly laid out in graded roads and paths beautified with tropical shrubbery of all kinds, and embowered in a grove of rubber trees and royal palms. Twenty years ago, under the French, it soon became infested with yellow fever, and every poor Frenchman who came in from whatever cause contracted yellow fever, and more than half of those who contracted this disease died. I was informed through the old superintendent who was in charge at the time, that in one day they lost from yellow fever three of their medical staff and in the same month nine of the same body. Of the 36 sisters whom they brought over as female nurses, 24 died of yellow fever. One of the chiefs of our supply department who came over in the early French days told me that he was one of 18 young French engineers who came over in one vessel; that in a month after their arrival all had died but himself. I am merely mentioning these details to show how different the circumstances are at present.

For nearly two years now we have constantly had yellow fever in these wards; the nurses and physicians are all non-immunes, yet not a single case of yellow fever has been contracted in this way. The nurses never seemed to consider that they were running any risk in being with yellow fever cases night and day in these screened wards, and the wives and families of the officers connected with the hospital lived about the grounds in all directions with the knowledge that yellow fever is constantly being brought into the grounds and treated in the buildings contiguous to them. I do not say this at all in criticism of the French. Under the same circum-

* Address delivered before the American Society of Tropical Medicine, St. Louis, Mo., Aug. 18, 1905.

stances twenty-four years ago I doubt if we could have done any better, but the knowledge acquired by Reed's board and Finley's persistent propaganda, have enabled us absolutely to exclude all probability of any contraction of the disease in our hospital. An American sick from any cause at Panama has no fear whatever of being treated in the bed next to that in which his companion is being treated for yellow fever. Dr. Carter and I live in the old ward used by the French for their officers. In this building, I suppose it is safe to say, more men have died from yellow fever than in any other building of the same bed capacity at present standing. We have our wives and children with us. Ten years ago I would have thought this the height of recklessness, but to-day, by taking precautions which are now recognized in yellow-fever work, we all look on ourselves almost as safe as we would be here in Philadelphia. In the yellow-fever wards the additional precaution is taken of putting each new patient in a wire cage just large enough to cover his bed. Here he is kept until the infectious period of the disease has been passed. Of course, in so important a matter as treating yellow fever in a general hospital, no possible chance of the spread of infection can be taken, so that in addition to every possible measure for keeping mosquitoes out of the ward and away from the yellow-fever patients, we also fumigate these wards every two weeks, so that if a mosquito should get in and bite a patient she would not have time to become herself infected. You will recollect that a period of time of from twelve to fifteen days has to elapse from the time that the female stegomyia bites the yellow-fever patient till she herself becomes infected and is able to convey the disease; therefore, if we fumigate every two weeks we would catch all mosquitoes before they had time to do harm.

The case having been reported in the city and the patient having been removed in a screened ambulance to the hospital, orders would be given from the central health office to the proper fumigating brigade to fumigate this house and all the contiguous houses, with the intention of killing the mosquitoes who gave the disease and also those that had bitten the yellow-fever patient, and if left alone would become dangerous in a couple of weeks. The stegomyia is a very domestic mosquito and generally does not leave the house where she is born and bred and does not stir much from the room where she has lived; probably the fumigation of the house itself would catch all infected mosquitoes, but as an additional precaution the contagious houses were taken, so that if by accident an infected mosquito had drifted from her original locality, she would be caught. The fumigating squads were composed of an experienced foreman and twenty men. They carefully pasted the house just as one would if one were going to disinfect with formalin. The fumigating material generally used was sulphur, sulphur being decidedly the best mosquitoicide we have, but in many buildings, such as stores and the better class of residences, there are many articles that are seriously injured by sulphur. In such cases we see Persian insect powder, pyrethrum; but in the use of pyrethrum care has to be taken that the mosquitoes are swept up and destroyed immediately after the fumigation. If this precaution is not taken a few may revive and again become dangerous. The patient is not forced to go to the hospital if he does not so desire. If he elects to be treated at home, the central office is so informed and the carpenter squad, who have screens on hand prepared for this purpose, are ordered down and screen the patient in so that he is protected from mosquitoes and those that

are in the room can not get out. Only one exit is left the room, a guard is placed who keeps the key of the door and only allows those in and out who are authorized by the physician. The fumigation in the rest of the house is then finished and the screened room is fumigated when the case has terminated.

As I have just stated, the stegomyia is a very domestic mosquito. She is very cleanly in her habits and breeds principally in clean rain water. In Panama the population have depended principally on rain water for domestic purposes, so that every house had cisterns, water barrels and such receptacles for catching and storing rain water. These we had to cover so that mosquitoes could not have access to them; for this purpose the city was divided up into small districts with an inspector in charge of each district. This inspector is required to get around his district at least twice a week, and make a report on each building with regard to its condition as to mosquito breeding. All the cisterns and water containers in Panama have now been covered and in the water barrels spigots so placed that the covers do not have to be taken off when water is drawn. About the first of March, when the first inspections were made, in the neighborhood of 4,000 breeding places were reported. On the last of October, when the last inspection was reported just before I left Panama, less than 400 receptacles containing larvae were recorded. This, I think, will give you a fair idea of the decrease in mosquitoes through the City of Panama.

In the City of Panama we found by count that 90 per cent. of the mosquitoes were stegomyia. This is another point in which we greatly differed from Havana. In Havana we found by count that only about 5 per cent. of the mosquitoes were stegomyia. This about covers the ground of the methods adopted for controlling yellow fever. Of course, you can see how very important it is for us to get hold of every case of yellow fever as it occurs; particularly is this the case at present, when it has about disappeared. The governor has offered a reward of \$100 for any case of yellow fever reported to the authorities. Between Panama and Colon there are some twenty villages running from 500 inhabitants up to 3,000; yellow fever in the last year has occurred at several of these villages. A queer thing about yellow fever is the fact that the natives in a locality where it frequently occurs are entirely immune, and not liable to contract a disease, so that in these small towns it is only the American employé who can have yellow fever. They usually live in frame buildings, well separated from the surrounding buildings, and it is a very simple thing to fumigate such buildings at once when a case occurs, and to get rid of the disease. We have not had a single instance of failure in disinfection in any of these small towns.

The results of this work have been the apparent elimination of yellow fever. In June, on the zone, we had 67 cases, in July 40 odd cases, in August about 27 cases, in September about 7 cases, in October 3 cases, and none in November and none so far in December. In the town of Colon our last case occurred July 23. Of course, it would be too early to say that yellow fever had been entirely eradicated from the Isthmus. This can not be affirmed with any certainty until the full life of a female stegomyia mosquito has been passed since the last case. In Havana, at Las Animas, we had a female stegomyia mosquito live in captivity for 150 days. So I think we ought to let at least two months pass without a case before we can say with any certainty that yellow fever has been eliminated. The same measures for the control

of yellow fever, and the extermination of the stegomyia mosquito were taken at Colon and at the various places along the line of the canal. While yellow fever has a great moral effect on the force, and was more important from this point of view to us than any other disease, malaria was the disease that had always caused the greatest loss from disability, that is, in a large force of men more days were lost from work on account of malaria than probably from all other disease put together.

My paper has already extended to such lengths that I can not go into a detailed description of the measures taken against malaria. They were the same as those outlined at Havana, and that are now so generally in use in the United States, principally superficial ditching. The results have been as satisfactory as they were in Cuba. In October we had a force of 22,000 men on our pay roll; of this number 21 per thousand were sick daily. This is an exceptionally small sick rate, very much less than is the average for our army in the Philippines. I think it safe to say that we are now digging the canal with as little trouble from sickness as would be the case if a similar number of men were engaged in a similar project between Philadelphia and Baltimore, and I see no reason why this rate should not be continued or even improved on. Water supplies are being put in, sewage systems constructed, houses repaired and built, food supplies and cooking arrangements constantly improved.

MEDICAL FORGERIES.

S. D. VAN METER, M.D.
DENVER.

It is fortunate for society that most of us are not familiar with the many disheartening pages of criminology, because we experience sufficient disappointments early in life to shake the most optimistic faith in

Fig. 1. Altered diploma of George A. Elliott. Identification is unquestionable, as it bears the Colorado Registration Board's inspection mark on its reverse side. This document was hanging in Ryetzel's office when arrested in Chicago by the federal authorities.

human nature; but there are certain phases of moral perversion of which but little is known to the expert criminologist, much less to the general masses. Untrodden ground is always interesting, and especially so if publicity of the unknown discovered there can benefit mankind.

The study of the many medical forgeries and frauds that are perpetrated on the unsuspecting public throughout the world, but more especially in this country, where our laws regulating the practice of medicine are so ineffective, offers a field for investigation replete with examples of moral turpitude comparatively unknown to the medical profession and of which the general public has no conception. If such were not true public opinion relative to the suppression of charlatanism would not be what it is to-day. When a traveler is relieved of his purse by the highwayman the people are up in arms and ready to mete out the death punishment without aid of court or jury. How different is the situation when those entrusted with the administration of our medical laws try to punish these robbers of the credulous sick!

The public is prone to assume, without investigation, that the medical boards are prompted by professional spite and jealousy in such prosecutions; and without the support of public sentiment the best law is seldom operative. It seems incredible that any one could be so

I have long entertained the opinion that if people had the faintest idea of the frauds being perpetrated by this class of criminals the existing public sentiment in relation to the enforcement of laws regulating the practice of medicine would be entirely changed. To this end a brief epitome of the following cases selected from those coming under my observation will, it is hoped, serve to illustrate the degeneracy of medical forgers, aid in bringing some of them to justice, and perhaps save a few unsuspecting mortals from their merciless clutches.

THE RYETZEL CASE.

In the spring of 1902 a man claiming to be George A. Elliott, M.D., University of Toronto, 1896, presented to the Colorado Medical Board for registration a genuine diploma of that school, name and date. The diploma was not questioned as to genuineness, and the board, after requiring the customary affidavit and payment of

fee, issued a temporary license. The authentication investigation of the applicant's credentials, while not conclusive, led us to believe that he was the person to whom the

diploma had been originally issued, and at the following meeting of the board he was granted a permanent license. He immediately opened an establishment in Denver which purported to be a private surgical hospital for women. The advertisements in the daily papers, however, at once revealed its true character. The Colorado medical statute had no provision for the revocation of a license except on the ground of the conviction of the licensee of conduct of a criminal nature, so that our board was powerless to revoke his license. We still supposed he was a man of ability, but one who had fallen from ethical practice.

In a short time he made application to join the Colorado State Eclectic Medical Society, and the committee on admission inquired at the office of the Colorado State Medical Board as to his credentials, graduation, etc. The fact that the University of Toronto was not an eclectic school immediately suggested that this man could not be the original Dr. Elliott. After a prolonged

search the real Dr. Elliott was located in Leamington, Ontario. Before we could get out papers for the arrest of his impersonator the latter was jailed on the charge of criminal operation on the person of a Miss Sarah Vance, the unskillful technic of which had caused her death. In his attempt to cover up this deed he frightened the girl's fiancé into suicide and tried to secure interment of the body by signing the burial certificate as one of death resulting from hemorrhage of the stomach due to gastric ulcer. He was allowed bail, which he promptly "jumped," and had it not been for the fact that the United States postal authorities had a case against him for sending immoral literature through the mails it is very probable he never would have been compelled to stand trial for this fiendish murder, which, according to one of his accomplices, was one of many.

Investigation of this impostor's record revealed that his right name was Albert Edward Rytzel, originally from Chicago; that he had served a sentence for larceny in the Illinois State Reformatory (Pontiac) as Charles Fox (No. 2865), from which institution he was paroled June 11, 1898, to D. K. Carter of Chicago. He reported once after being paroled, then ran away with \$40 and assumed the alias of Dr. Bennett.

Under this alias his record is not very complete. In 1900 he appeared in Kansas City, Kas., as Dr. George A. Elliott, where he conducted a place similar to his Denver institution. While in Kansas City a Swiss midwife, Adele Cornely-Cachoud, was supposed to be his wife. She came with him to Colorado, but his affections were soon transferred to one Mary Etta Inman. To get rid of the Cornely woman he induced her to send some immoral literature through the mails. As soon as she was arrested he arranged for her bond and then persuaded her to return to Switzerland. He was not shrewd enough in this scheme, as the federal authorities arrested him as her accessory.

After forfeiting bail in the Vance case he discovered that George E. Cooke, who was graduated from the University of Toronto in 1896, had qualified and located in Chicago, and later, like George A. Elliott, had returned to Canada. Rytzel then erased the name of Elliott from the University of Toronto diploma in his possession and substituted that of Cooke, assumed his fourth known alias, and commenced practicing in Chicago under the name of George E. Cooke, who the records in Springfield showed had been duly licensed. The postal authorities were too keen, however, and he was soon caught and turned over to the criminal court in Denver to stand trial for the criminal operation and murder in the Sarah Vance case. He was tried and convicted on the first charge, fined \$1,000 and sentenced to the penitentiary for three years at hard labor. When he has served this sentence he will have to stand trial on several other charges, and it is to be hoped that he will be kept for many years where he can not endanger the lives of the unwary.

As soon as the Cornely woman returned to Switzerland he married Mary Etta Inman, although Adele Cornely was at least his common-law wife. He caused to be published in *The Journal of the American Medical Association* of July 12, 1902, an announcement of his marriage to "Viola A. C. Cornely, both of Denver," notwithstanding that at the time she was on her way to Switzerland, and further that the records in Denver show that he was married to Miss Inman on July 18, 1902. It has been ascertained that his marriage to Adele Cornely was a mock ceremony and that he had also been married in Chicago to a Mary Kaurin in February, 1902.

He induced Miss Inman to make false representations to the Colorado License Board and to secure thereon a fraudulent certificate (No. 3865), which she was compelled to cancel, as is shown in the reproduction of such cancellation. While in Chicago under the alias of Cooke he made application to the Oklahoma State Medical Board, and had the undaunted nerve to use the name of so prominent a surgeon as John B. Murphy as one of his sponsors. It does not require the aid of an expert to see that the signature purporting to be Dr. Murphy's is in the same handwriting as the cancellation of Mary Etta Inman's registration.

The exceptionally good imitation of George A. Elliott's signature Rytzel succeeded in making is conclusive that he had in some manner secured a sample of the latter's handwriting as a copy. How he obtained the Elliott diploma is as yet unsolved, but if the story of Mary Etta Inman is to be believed, certain individuals holding positions of honor in their respective communities should feel a sharp prick of conscience when they read this article.

Rytzel's demeanor as a criminal before the bar of justice is one of coolness personified. Thief, forger, murderer and bigamist, fiend incarnate as he is, he is different from the ordinary criminal. Unquestionably he is a degenerate, a man who is most dangerous to himself and society, one who, if there is not sufficient evidence to cause his execution, should certainly be kept under restraint. His scrapbook, filled with clippings of his own and similar advertisements, is a rare collection, notwithstanding its worthlessness save to those engaged in the same unlawful occupation, as a book of reference for style and diction.

This résumé of Rytzel's known record is not complete, but it is sufficient at least to give a fair idea of the depravity of a man who, that he might satisfy his base desires, stopped at nothing and lived principally by the murder of innocents. With all his hardened conscience, the ordinary murderer would shrink from such deeds and blush for shame.

THE CORY CASE.

During the summer of 1900 a woman assuming the name of Dr. Emma W. Cory applied to the Colorado Medical Board for a license to practice medicine. As evidence of educational qualification she presented a certificate from the secretary of the medical department of the University of Michigan to the effect that one Emma W. Mooers had received the degree of doctor of medicine from that institution in 1884. She set forth in her application affidavit that her maiden name was Mooers; that she had married a man by the name of Cory, and that she had lost her diploma by fire. She was granted license (No. 3206) and began to practice under the name of Cory. Her subsequent actions, as is usually the case with this class of impostors, convinced the board that she was a fraud. However, suspicion without proof is worthless, and after considerable search for the original Dr. Mooers, we dropped the case.

Not long afterward Dr. (?) Cory chanced to meet Dr. Laura L. Leibhardt, a classmate of Dr. Mooers, and in the course of conversation inadvertently made the statement that she was graduated from the University of Michigan in the class of 1884 and that her maiden name was Emma Mooers. Dr. Leibhardt recognized that she was an impostor and reported her to the board. To make a clear case it was necessary to find the real Dr. Mooers. We renewed our search and located her in Waverley, Mass., where she was pathologist to the McLean Hospital.

At the preliminary trial Dr. (?) Cory held fast to her claim that she was the Emma W. Mooers who was graduated from the University of Michigan in 1884. When questioned as to how it happened that she was not lame, whereas the Emma Mooers known to Dr. Leibhardt was, she admitted that she had been lame, but claimed by a certain course of treatment to have been entirely cured. She was bound over to the district court, where she was convicted and sentenced to one year in state's prison. On account of her sex and her children the court allowed her to go on parole. Soon after the expiration of her sentence she embarked once more as a would-be disciple of the healing art, but this time as an Eddyite.

At the trial in the district court Dr. Mooers appeared as a witness, although it necessitated a trip of 5,000 miles, made possible by the aid of the medical faculty of her alma mater. It did not take the court and jury long to decide between the real and the impersonator—the one a lady of culture and refinement, the other a base, degraded criminal. It was subsequently learned that Dr. (?) Cory had impersonated Dr. Mooers in several other states and had succeeded in eluding the officers, making good her escape each time when hard pressed. These successes explained her boldness when arrested in Colorado. From her advertisements it was plain to be seen she was engaged in the same nefarious work as Rytzel.

THE WARREN CASE.

Unquestionably this case is one of the unique examples of medical forgery, or to be specific, graduation by proxy, on record. The star of this little drama is Dr. (?) Augustus H. Warren of Chicago. Owing to the defective medical statute he cannot be disturbed so long as he remains in that state, nor can the Illinois State Board of Health revoke his medical license, known to have been fraudulently obtained, if their present construction of the law is correct. He originally hailed from Indiana, Pa., where he was accused of arson to secure insurance money. From Pennsylvania he drifted west in the early eighties, and for several years was "barker" for a traveling medical faker. The opportunities this position offered for observation of the gullibility of the public in matters medical no doubt convinced him that a better field did not exist wherein he could obtain money under false pretenses than in that of quackery. To succeed, however, he must possess a medical diploma, and the story of how he obtained it reveals a talent for scheming worthy of use in a better cause.

The records of the Omaha Medical College show that in the spring of 1885 one Sidney H. Knowles was graduated from that institution. In the fall of that year he appeared in New York City under the alias of A. H. Warren, where he matriculated in the graduating class of the medical department of the University of New York as a graduate of the Omaha Medical College, 1885. At the time of this matriculation he gave his age as twenty-six, which compares with that given when he entered the Omaha Medical College in 1884. Inasmuch as the records of the Omaha Medical College show that no one by the name of Warren ever matriculated in that institution, it is conclusive that Dr. Knowles must have used his notice of graduation, or some similar credential, changed to the name of Warren, when he matriculated in the University of New York. He was graduated from that university in the spring of 1896 and turned his diploma over to Warren. We are informed that Warren stood the expenses of Knowles while in New York and gave him \$1,000 for the diploma. Rather a profitable winter's work, when a postgraduate course at one

of the best medical colleges in the country is considered. Knowles went west and practiced on his Omaha diploma. When last heard of he was in Bremerton, Wash., but like the history of all evil-doers, his life has been full of thorns. Verily, verily, "the way of the transgressor is hard"!

Warren succeeded in gaining legal standing as a physician in six states on the diploma issued by the University of New York to Knowles as A. H. Warren. Since passing out of my hands, however, it is not likely this diploma will be presented to another license board, inasmuch as the red-ink inscription on the face thereof would be decidedly detrimental to the chances of the applicant presenting it.

Warren used every scheme known to the charlatan in fleeing his victims, but his special method was to have an advance agent proclaim his coming as a renowned physician particularly skilled in the cure of cripples and incurables. He advertised not only "no cure, no pay," but declined to take any money until the cure was satisfactory to patient or guardian. By this means he could secure the promise of a larger fee, and in making his contracts he used an ingeniously devised note drawn so as to read that it became null and void if for any reason the signer was dissatisfied with the result in the case under treatment. This part of the contract was so cleverly arranged that it could be torn from the rest and leave a straight negotiable note. After securing as many such notes as he could in a community he would take them to a bank and dispose of them by allowing a liberal discount. So clever a man is he that in one rich farming district alone, with only two weeks work, he departed to pastures new with \$2,400 gathered in. It is needless to say he never returned or sent further recommendation as to administration of medicines he left, which on analysis proved to be principally common salt and water, with a little inert coloring matter added to disguise them.

THE HAGEN BURGER CASE.

Degeneracy with criminal inclination is dangerous enough when co-existent with the manners and facial expressions of a criminal, but when discovered in people of genteel appearance, pleasing address and good physiognomy it becomes a much greater danger to society. Such characters are occasionally seen in all classes of criminals, but nowhere in the annals of medical forgery can there be found a better example than in the person of a man who claims the name and titles of Dr. med. Gottfried Leonhard Hagen Burger, M.S., Ph.D., F.R.C.P.S. (King), of 867 Beacon Street, Boston.

This wonderful medical savant's history, so far as can be determined, does not, like most noted men, commence with the date and place of birth, parentage, etc., because it is impossible to trace it further back than the early eighties, when he was graduated from the American College of Veterinary Medicine of Brooklyn. After graduation he opened in that city a veterinary hospital, which he subsequently sold. He then took up the study of law, but soon chose medicine as the profession he would assume, and after a few months spent in visiting European clinics, we find him in Helena, Mont., claiming to be an M.D. from the University of Kiel, Germany. His career in Montana was of short duration, notwithstanding it was full of tragic and dramatic experiences. How he passed the examination and secured a license to practice in that state is difficult to understand when certain facts relative to his forged credentials and lack of educational and moral qualifications are considered. By whatever manner or means it was accomplished the

incident serves as an object lesson which proves that the mere possession of a diploma, without proper authentication and careful scrutiny, as a prerequisite to admission to state board examination is not all that advocates of such a statutory provision claim.

His career in Montana as a self-styled specialist in abdominal surgery came to a climax when he performed his first celiotomy on Mrs. A. J. Schumacher, the wife of a prominent mining engineer of Butte. She promptly died and her husband came near bringing Herr Hagen Burger's earthly career to a sudden and tragic end. It was not so ordered, however, and with aching bones and bandaged wounds he left the state between suns.

A few months later he made his debut in Colorado. His failure as an abdominal surgeon had veered him to another line of practice. At that time he was overflowing with personal proclamations of his skill and experience.

Fig. 9.—A. Edward Rytzel as Dr. George E. Cooke when arrested in Chicago by the United States postoffice authorities, June 6, 1903 (reproduction from a newspaper picture).

as a medical practitioner, disclaiming any predilection for the surgical side of the profession. His special hobby was a great invention of a room in which the atmospheric pressure could be controlled. By such a contrivance he proposed to procure for pneumonia patients in high altitudes an environment exactly the same as produced by the natural barometric conditions at sea level. He lost no time in calling on the secretary of the State Medical Board, ostensibly to inquire of the requirements for licensure, but in reality, like the ordinary bunco man, to size up the secretary, because, as was afterward discovered, he was thoroughly informed as to the provisions of the Colorado law. He claimed to be a graduate of Kiel and Wurzburg, but stated that as there was some uncertainty about his locating in Colorado, he would not make application for license; that

he was on his way to New York to see about the manufacture of his pneumonia room, and should he decide to return to Denver he would then file his application and credentials.

It must be confessed that in spite of my self-esteem as a reader of human nature, this man, with his suave manner and general appearance, deceived me completely. I put him down as one of those pseudo-scientific cranks who think they are going to revolutionize the accepted theory and principles of practice. On his return he took particular care not to come near the office of the medical board, although he had the audacity to open an office in the leading hotel in Denver and send out a card to the medical profession (excepting the members of the medical board) announcing himself to be specially prepared to conduct all kinds of clinical examinations, and

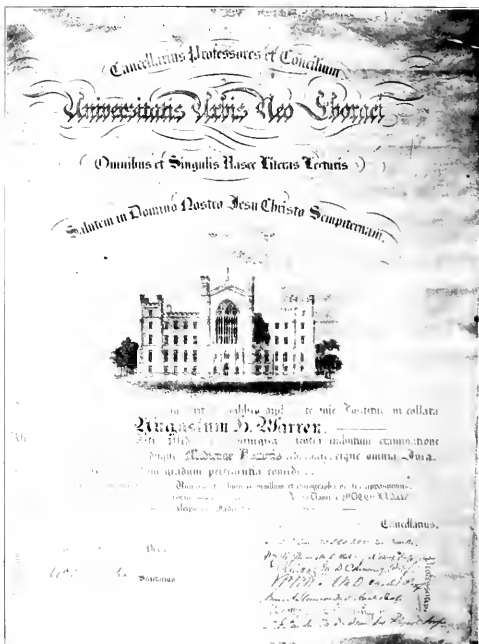

Fig. 10.—Reproduction of diploma issued by the University of New York to Sidney H. Knowles as Augustus H. Warren.

that he would limit his practice to the "diseases of the stomach, abdomen and chest." As evidence of his qualification he added the following:

- Late assistant with Chauta and Chrobak, Vienna.
- " " Ewald, Boas and Baginsky, Berlin.
- " " Leopold, Dresden.
- " " Kehler, Heidelberg.
- " " Koch, Senator and Rosin Charity Clinic, Berlin.
- Late assistant with Leube and Maerstock, Wurzburg.
- " " Fisher Col. Uni., New York City,
- C. P. and S.
- Late assistant with Cabot and Hewes, Harvard Laboratory, Boston.

The idea of being "Late Assistant with" eight prominent medical men from Berlin to New York is too inconsistent to need comment. The board's first knowl-

edge that he was practicing in Colorado came in the form of an inquiry from the city health officer asking if he was a licentiate in medicine in Colorado. He had been arrested for reporting a case of smallpox as typhoid fever. As he had not even filed an application for a license, we notified him that unless he immediately complied with the medical practice act he would have to answer a charge of practicing medicine without a license. His application was forthcoming, in which he made a sworn statement to the effect that he was a medical graduate of the University of Kiel, 1896, and an M.D., Ph.D., Wurzburg, 1887. In support of his affidavit he presented two documents, one from Wurzburg, purporting to grant the combined degree of doctor of medicine and surgery and doctor of philosophy; the other from Kiel, conferring the degree of doctor of medicine and surgery. As our statute allowed no recognition for a diploma conferring the combined degrees of Ph.D. and M.D., the Wurzburg diploma was returned to him, but we kept the Kiel document.

Fig. 11.—Reproduction of the diploma of Dr. Otto Tretow from the University of Kiel. Note the special type, the large white in-press seal and the dean's signature in Latin script.

Owing to the general appearance of his credentials, which were poorly printed on inferior paper, our suspicions were aroused and special investigation made of his credentials. Through the kind assistance of Professor Helferich, dean of the medical department of the University of Kiel, Hon. Paul Gaston, United States consular agent of Kiel, and Professor Baumann, of the University of Wurzburg, we were able to establish the fact that both documents presented by this impostor were forgeries. That from Kiel, with the original from which it was copied, are here reproduced. The Colorado board naturally refused to grant him a license on such credentials and had him arraigned in the criminal court for offering false and forged evidence in applying for registration.

In addition to his general suavity, augmented by an

unfailing nerve, Hagen Burger possessed an exceptional gift of enlisting the aid and sympathy of the gentler sex. This accomplishment he used to advantage in securing bail. It enabled him to deceive the wife of one of the most prominent and honored members of the Colorado bar. This gentleman was induced to go on Hagen Burger's bond temporarily, but his liability proved to be permanent. The state was confronted with the difficulty of securing a witness competent to identify the genuine signature of Professor Werth, and Hagen Burger became confident he would be acquitted by our failure to get such witnesses. The law's delay was irksome and his opportunity to gull the Denver public was suspended by the pending charge.

On July 1, 1902, he made the bold move of appearing before the board for examination to show educational qualification entitling him to a license. Under our statute we could not, even had we desired, refuse to examine him, notwithstanding the abundant documentary

Fig. 12.—Reproduction of forged Kiel diploma by G. L. Hagen Burger. Comparison shows it to be an exact duplicate of Dr. Otto Tretow's as to date and title of thesis, but the paper, type, printing, seal and signatures are entirely different. The signature of Professor Seelig, the rector, appears with that of Professor Werth, in German script and in the same handwriting, while it is customary for only the dean to sign medical diplomas, and then always in Latin script.

evidence in our possession of his bad moral character. In filling out the customary examination blank he carefully avoided mentioning having studied at Wurzburg and Kiel, but claimed to have attended lectures at Heidelberg, Vienna, Dresden, Harvard University, New York Post-Graduate and New York Polytechnic. No record in any of these cities or at any of these institutions can be found where he regularly matriculated, although he attended the clinics in some of these cities, which, without previous preparation, did him about as much good in an educational way as the country bumpkin who went through college by walking in at the front

door and out the back the same morning. He was carefully watched during his examination and his papers liberally graded to prevent accusation of bias on the part of the board. His knowledge on the subjects of examination, however, as evidenced by his vague and indefinite answers, was so superficial and wanting in essentials we were compelled to refuse to grant him a license. His answers to ten practical questions in anatomy showed an absolute ignorance of the subject. In his "stabbing" attempts to name the muscles attached to the greater trochanter of the femur he only succeeded in mentioning two, and those by the name used in comparative anatomy, which he evidently recalled from his veterinary course of instruction. When notified of his failure to pass the required examination he forthwith began mandamus proceedings in the district court to force us to grant him a license on the grounds that the board was guilty of prejudice and partiality. The real motive in taking the examination and in instituting the mandamus suit was soon made clear by a proposition from his attorney to drop the suit, provided the court would *nolle* the criminal complaint.

Meeting the deserved disappointment in this move, and realizing that the board had been successful in securing three graduates of Kiel as competent witnesses to testify to Professor Werth's signature, Hagen Burger informed his bondsmen that he had come to the conclusion that what he had believed to have been genuine examinations by the Kiel and Wurzburg authorities were probably fraudulent schemes imposed on him by a band of counterfeiters to secure the examination fees; further, that if he could be allowed to go to Germany he could establish the fact that he had been so victimized. How such a flimsy transparency could have gained credence in the mind of so able a jurist as his bondsman is beyond understanding. Nevertheless he allowed this scamp to start on his journey, ostensibly to Kiel. He failed to get further than the Atlantic coast, and soon the report came back that he was under the care of several of Gotham's most eminent neurologists for an attack of nervous prostration of such gravity that it was probable death would take his case from the jurisdiction of the Colorado courts. The Grim Reaper was not so merciful, however, and we next hear of this impious wretch in Boston, at which time, judging from the character of the following advertisement from the *Boston Medical and Surgical Journal*, he had completely recovered from his attack of nervous prostration:

PRIVATE COURSE ON PHYSICAL AND CLINICAL DIAGNOSIS. Class limited to eight members. Six weeks individual instruction. Abundant dispensary material. Price, \$20.

COURSE ON OPERATIVE GYNECOLOGY.

Six on the endartery. Price, \$25.

Also preparation and quizzing for State Boards, Army, Navy, and Hospital Examinations.

Dr. Med. G. L. HAGEN BURGER, F. R. C. P.

(King.)

867 Beacon St., Boston.

At least his old-time effrontery and desire for unearned professional titles had reasserted themselves. Investigation at once revealed why he had become so bold. He had, by some means, succeeded in passing the Massachusetts medical board as an undergraduate, and thereby gained a legal standing in that state, as he had in Montana as a graduate of Kiel. With any knowledge of his cunning and fearlessness it is easy to understand how he succeeded in deceiving the Massachusetts board, but, so far as can be learned, they have taken no steps to remedy the error they made by granting this arch-moral impostor a license to practice medicine in the state and city whose very name is synonymous with

higher education. Through some agency he has circulated in Denver the story that he was teaching medicine in one of Boston's best institutions, where his scholarly attainments are recognized, in contrast to the lack of appreciation exhibited by the profession in Colorado. In view of the man's history we think this story pretty hard on Boston—at least Colorado can stand it.

Later it was discovered that he had been admitted to membership in the Massachusetts State Medical Society as a graduate of Queen's College, Kingston, Ontario, 1904. Investigation revealed that when he was reported to be under treatment in New York City for a shattered nervous system he was attending lectures at Queen's College, where he had matriculated in the senior class as a graduate of a German university, probably Wurzburg. The dean of Queen's College states that he failed on his first examination, but was passed on the second. Their senate is now conducting an investigation of the case, in which those of their faculty in charge of matriculation and examination of candidates for graduation were most ingloriously duped, and to do other than to revoke the diploma granted Hagen Burger by their college would gain that institution a most unenviable reputation with the medical boards throughout the world.

In studying Hagen Burger's character and deeds one can not help being impressed with his apparent total disregard for the consequences of his wrongdoings. This is so manifest that his sanity can well be questioned. There is so much method in his madness, however, that he should be made to feel the heavy hand of the law. Owing to the expense of extradition, and a most apparent disinclination on the part of the state's attorney to push the Colorado case against this scoundrel, it has been impossible for our board to do anything more toward his prosecution. The mandamus case against the board was dismissed when he discovered it would not accomplish his purpose. When such a man can do what he has, in the way of deceiving medical boards and the public, can any one advocate the lack of necessity for the most stringent laws regulating the practice of medicine? Certainly not, and it behooves the people that they lend every effort to assist in the enforcement and betterment of such statutes.

CONCLUSION.

The natural conclusion to my description of these examples of depravity would be an exposition of the means by which the people may protect themselves from the ravages of such medical impostors. It is possible to eradicate them and render their further appearance in society an impossibility, would the public conscience but awake and give heed to their outrages and resort to the strong arm of the state to control the practice of medicine. The establishment by law of a few sensible and obvious regulations for the government of those who hold themselves out to the public as qualified to heal the sick would eliminate from among us this class of criminals now plundering the credulous and dealing death to the feeble and disconsolate who innocently fall into their murderous hands in their aimless search for health. Here there is a grave duty to perform, and it rests heavily on the shoulders of the educated men and women throughout this broad country.

Specialism.—Dr. J. F. W. Whitbeck, in the *American Journal of Obstetrics*, says that specialism in medicine has been carried so far as to have almost caused the passing of the family physician, a condition which he deprecates.

WASHINGTON, D. C.

This article is not written with the thought that a summer's sojourn in these regions is, or can be, infallible as a curative measure or that it can be beneficial in all varieties of cases, but, as some localities are unhealthy while others hold elements which favor health,

fall directly on the near segment of the polar area and likewise pass over and beyond the pole even to the distal are of the arctic circle. The rotation of the earth brings each point on the circle only to the edge of the shadow, and so no spot included within the circle passes out of the direct sunshine. In December, when the earth is on the opposite side of its orbit, the north pole leans away from the sun, and its rotation does not bring any spot in the polar area to face the sun, so these regions are then constantly in the shadow, or night. In passing the intervening quarters of the orbit the axis is inclined sideways from the sun, so that the borderline between light and shadow passes over the poles. Consequently, at the pole the sun rises but once and sets but once in each year; six months have sunshine and six months have none. Southward the months of continuous sunshine

became shortened until, at the Arctic circle, the longest period through which it lasts is twenty-four hours.

In the transitions from season to season the course of events is as follows, the exact time of these changes at any one place depending on the latitude: About the first of September the sun begins to dip daily below the northern horizon at our usual midnight hour. There is no darkness, but the twilight of the sunset and the dawn merge one into the other. The sun's rising and setting occur each day more around to the eastward and westward: as it remains longer below the horizon the night begins to encroach on the day, until on September 22 the two are of equal length. The sun continues its southern swing so that in December it comes above the horizon just east of south and drops out of sight again just west of south. The next day it does not show at all, and for a period the night is only relieved by a twilight at noon in the south.

At last, even this does not show and there is the continuous cold and cruel Arctic night of winter. In February the southern twilight shows again; later the sun appears for a few hours daily. The daylight lasts longer and longer as the sun in rising and setting works around the compass until in June it both rises and sets again to the northward. Then, after one short final dip below the horizon, it sets no more, but completes its circling each day in the heavens overhead.

In these months the darkness and cold of the night disappear in the warmth and life of daylight, extending without cessation through several months of time.

In the forepart of this long day the snow melts and the ice is broken up and carried away by the winds and tide. In July naught distinctive remains to impress on one that he is in Arctic regions, except the midnight sun and the glaciers which, pushed forward by the weight of ice in the perpetually frozen interior, throw off bergs of ice into the sea. All else is indicative of pleasant summer as the frozen life leaps into flowering vegetation under the stimulating sunshine.

Meteorologic data of a cruise from Sydney, Cape Breton, Nova Scotia, to 75 degrees N. Lat. in Greenland.

so also are certain conditions recognized as favoring improvement in pulmonary tuberculosis. These conditions may be utilized better by a sojourn at places where there is a full combination of health-inviting conditions.

This data does not deal with the days and nights to which we are accustomed. Most of it should be regarded as showing the conditions during a succession of twenty-four-hour periods making up one single day several months long, for such is the arctic summer. This happens because the earth's axis is never perpendicular to the plane of its orbit. Thus, on June 21 the north pole is tilted about one-fourth toward the sun, whose beams

conditions during such an Arctic summer. It is compiled from my records on the *S. S. Erik*, the auxiliary vessel of Commander Peary's present polar expedition, on which I went north for the third time to obtain certain information which perhaps may aid in making these lands accessible to the tuberculous. The vessel cruised according to her special purposes and there was no selection of places with regard to climatic conditions. The arctic waters were entered a month past the summer solstice, and so the chart but depicts conditions toward the close of the summer day.

The weather of the first week, in passing Newfoundland and Labrador, was worse than that usually met at this time of year in more southern waters. In contrast to it is the latter part of the return trip over the same route. This is in accordance with the well-known changes of fog in these regions.

It will be seen from the chart how a few days suffice to bring one into the regions of ceaseless sunshine, where for months a clear atmosphere is the rule and

life-giving stimulus of two days' sunshine thus forced into one, but the value of the light is enhanced, as is shown by the accompanying photographs. Figure 1 was taken at 12 p. m., a snapshot from the moving vessel, the diaphragm used being one proper for exposures in our latitudes during the afternoon, when the altitude of the sun is much greater. The nearest land and glaciers were 10 miles off.

Figure 2 is an example of the deceptive perspective created by the clear atmosphere under certain conditions of light. It is an instantaneous exposure with a one-fourth inch diaphragm taken at 9 a. m. The iceberg is about $1\frac{1}{2}$ miles off, the glacier front about a half mile farther on and the receding gorge is over a mile in length, though to the eye, as well as in the photograph, all objects appeared to be about the same distance off.

Being previously aware of the peculiar actinic power of the arctic sunlight, a pin-hole camera, without a lens, was prepared as a test. In Washington this required a three-minute exposure. In northern Greenland, under

Fig. 1.—Snapshot of land ten miles distant, taken in Arctic regions at 12:00 p. m.

poor weather the exception. Starting earlier, one would have not one month, but two or even three months of this summer day.

The lines in the marginal brackets, during which days the vessel remained at anchor in the same place, are blank for the simple reason that hour after hour there was nothing to record—no haze, no fog, no clouds, no wind, no darkness, nothing but a succession of hours of brilliant sunshine. The first series was at 76.5 degrees north latitude in North Star Bay, a small basin bending in from Worstenholm Sound, eight miles from where the latter debouches into the open sea. The second series was at 78.5 degrees north, just within the entrance of Etah Fjord, which is protected by high hills of warm rock on either side. The blank spaces of these days show the difference between the atmospheric conditions on the sea and when but a few miles distant from the coast line.

The chart shows that away from the open sea there is nothing to obfuscate the sunshine. Not only is the

what seemed to the eye to be equivalent conditions of light, one minute sufficed, and an exposure of two minutes blackened the film. Though the quantity of the light appeared to be the same, its quality was altered; there was an increase of the actinic rays, and it should be borne in mind that these rays are allied to those which influence metabolism. Much of this increase of actinic effect may be attributable to the clearness of the atmosphere; indeed, one may at times see plainly objects seventy-five or a hundred miles away, but other facts indicate that a further explanation must be sought.

The hypothesis is advanced that there is a different proportion of the component rays in the sunbeams as they approach the poles or approach the equator. In laboratory experimentation it is known that magnetic fields deflect some rays having the more rapid vibration periods, and the earth, acting as a magnetic field, may so influence the stream of approaching sun's rays that some will be deflected from their straight course and crowded together toward the Poles.

The prolonged absence of light and the recurring scarcity of food each winter would lead to the extinction of life in the far north were there not compensations given in this protracted light of extra potency. As it is, the vegetation does wonderfully well in its struggle for existence, the native animals are the largest of their kind, and countless fowl from the south select these places to hatch and rear their young. The Eskimo lose flesh and strength during the scarcities of the winter season, yet with the returning light they recuperate quickly, become again plethoric and, as do the animals, accumulate a surplus of fat to carry over into the next depressing winter.

In these lands there occurs naturally on a grand scale all that we may try to accomplish by artificial aids in treating slow diseases in which periods of retrogression are liable to occur. The management of the favorable stages in such diseases is directed toward regaining the vitality already consumed by the disease and also, when possible, providing a reserve of strength to safeguard against the next period of depression. In many parts of the Arctic such a stimulation is exhibited for the fourth part of each year in every event of life, and it may be made serviceable in increasing chances of regaining health.

Concerning the temperature records, it may be said that readings were taken at 8 a. m., noon, 4, 8 and 12 p. m., and the thermometers were shaded and sheltered twelve feet above the side of the vessel to eliminate, as far as possible, errors which might be caused by heat from the vessel. Check observations showed but minor alterations from this cause.

Air itself, that is, the mixture of oxygen and nitrogen, can not be heated; the sunlight in passing through warms only the admixture of other gases, watery vapor, dust, etc., and this determines the temperature of the atmosphere. As the Arctic air carries no dust and the percentage, i. e., the actual amount of contained moisture is small, it remains cool, even under the ceaseless sunshine. This gives it a bracing quality that is not felt as cold, for when out of doors one always experiences the temperatures given in the next column of the chart. These were taken at odd times when the sun could beat through the open door of the observatory directly on the instruments. These figures show why one wears neither overcoat nor gloves in the arctic summer and how one may sleep comfortably out of doors if so disposed. The Arctic summer is pleasant; it is not warm enough to enervate; it is just cool enough to freshen one and to invite an invigorating life.

The limited range of the daily fluctuations in temperature is accounted for by the heat which is radiated from the rocks being taken up by the miles of glacier ice. This thermostatic action insures uniformity of temperature; there are no decided barometric "lows" and storms are rare in summer.

In the bracketed series of days, the relative humidity,

instead of remaining above the seventies, went as low as 28.08. The prevailing light winds are from the icy interior, and the atmosphere loses its surcharge of moisture as haze or fog along the coast. Had it been possible to take the observations a half-mile inland or even in some of the deeper penetrating fjords, the maxima of humidity would have been much less than those shown in the chart.

A comparison of the relative humidity at each of the places where the steamer remained for some days, with observations of the U. S. Weather Bureau during the same month of August at cities in different sections of our country, stands as shown in table.

The atmosphere of these places in Greenland during the stay of the vessel was never as moist as during the night and morning hours in each of these cities; it was never as dry as it became in three of them during the heat of the day; the range of variation was decidedly less, and the actual amount of contained moisture was smaller.

Fig. 2.—Snapshot of iceberg one-half mile distant, glacier one mile distant and gorge of a mile in length, showing deceptive perspective caused by clear atmosphere in Arctic regions.

In this connection it may not be improper to consider the influence which sea air, which is the air of accessible parts of the Arctic, may have on the tuberculous. A comparison of the tuberculosis ratio of the army with that of the navy may be useful, as in both services the

	Maximum Humidity.		Minimum Humidity.		Average Humidity.	
	8 a. m.	8 p. m.	8 a. m.	8 p. m.	8 a. m.	8 p. m.
New York	100	95	62	50	81.3	74.4
Washington	100	93	65	56	84.8	79.1
Los Angeles	100	80	52	23	88.1	62.1
Denver	90	40	41	13	66.1	37.1
Phoenix	88	50	43	15	59.0	25.2
North Star Bay	72	71	56	29	63.4	54.0
Etah	81	70	40	35	57.6	52.4

men are equally hearty on taking up the special life. The sailor sleeps in ship's quarters, does not get fresh food when at sea, his exposure is more severe, his sleep, duty and relaxation are set by watches instead of being naturally regulated by night and day, and when ashore

he is exposed to the infection even while breathing dusty air, to which he is unaccustomed. Considering the chances of the two, the sailor should succumb more often than the soldier, yet there is about an equal tuberculosis rate in both services. It seems, therefore, that a life near or on the sea has some influence in at least holding off tuberculosis infection, and so after infection sea air should be preferable if it can be had where there are no decided fluctuations of temperature or a high humidity to produce dampness, catarrhal conditions, etc. Such is the air of these lands. In all respects as to comfort it is preferable to the air of excessively dry regions.

On this short trip the crew, though engaged at habitual work and having the same food as on other cruises elsewhere, and probably not so good as at home, made an average gain of ten pounds in weight.

Concerning the classification of each day as to its suitability for semi-invalids, I consulted Prof. N. Senn, who also undertook the journey to complete his investigations of disease among primitive races by a study of the Eskimo of northern Greenland. As the vessel was covering some 200 miles each day, sometimes near land and sometimes at sea, we had to consider the general characteristics of the whole twenty-four hours, paying particular attention to the usual waking hours. When the weather was such that a delicate person would feel uncomfortable, or the day one which we could not consider beneficial, it was classed as unsuitable or No. 4. When most of the day was good, but with some hours of dampness or wind, generally in the night hours, it was classed as indifferent or No. 3. Days which had the full sunlight obtunded by clouds or were slightly overcast were called favorable or No. 2. These days were in reality fine days and only classed as No. 2 in order to reserve a class for the superexcellent days, in Group 1, whose perfection could not be equaled elsewhere. At each of the two harbors in the north there was a succession of these "excellent" days; this series, it may be said from past experience, had been repeating itself for two months and continued for some weeks after we left.

In the arctic there is a significant absence of affections of the respiratory tract. The following statements from leaders of experience may be interesting: General Greeley, in referring to previously published statements of my own,¹ writes: "My experience regarding the contracting of colds, is practically the same as that mentioned in your article." Also, Mr. W. S. Champ says: "From my experience in the arctic I thoroughly agree with you in regard to the climatic advantages to be met with in the far north." When one is chilled in wet clothing the physiologic reaction may sometimes be manifested by relaxed tonicity and engorged nasal membranes, but this is fleeting; there are no pathologic conditions of catarrh and no fever; in short, one can not "take cold."

The arctic atmosphere holds no dust and is sterile so far as noxious germ life is concerned. Sparse molds and a few harmless bacteria exist, but the low temperature does not favor the development of pathogenic organisms, and the constant sunlight will forever keep these lands free of contamination by imported diseases.

The merits of this climate for the relief of chronic affections, particularly tuberculosis, are threefold:

First.—It holds absolutely nothing to add fuel to the existing flame. There is no dust to irritate tissues al-

ready struggling against a present mastery of the disease, no superadding of pus or other infections, no contracting of colds to invite a setback, nothing to depress vitality.

Second.—It holds every incentive to an increase of bodily vigor. Each and every chance and opportunity for a cure which is here sought for and obtained only singly or indifferently is there grouped together in full intensity without the necessary presence of any disadvantageous element.

Third.—As a result of this dual combination, a beginning tuberculous process may be checked in the shortest space of time, and not so much local damage will be done while waiting for the tide to turn and recovery to begin. This will lessen the chances of a new infection occurring after a cure.

Since I have broached this subject I have heard from no one acquainted with these lands who does not corroborate these views. Dr. F. S. Nash, surgeon, U. S. N., who has contributed a monograph on the arctic, in a personal letter, writes: "My position as one of the surgeons of the Greeley Relief Expedition under Admiral Schley and afterward as surgeon of the Northern Alaska Exploring Company gave me excellent opportunities for observing the conditions of which you write. . . . most heartily indorse your statements." Mr. H. L. Bridgeman, a traveler of wide experience who has been to the places where the foregoing records were taken, considers them eminently suitable for a summer sojourn by consumptives.

Prof. N. Senn, the latest and most deeply observant of medical writers on the Arctic,² tritely summarizes the whole situation when he says that Nature there bends such efforts toward prophylaxis as to leave no need for therapeutics.

These lands can be reached without difficulty or danger; the pioneer work has been done and the way is open. Concerning this Commander Peary, who knows every detail of the Arctic in its pitiless moods of winter and its smiles of summer, wrote last August at Etah: "Answering your inquiry in regard to bringing a ship to this region for a summer voyage, I beg to state that the experience of nearly fourteen consecutive summers enables me to say that there is nothing more arduous in a voyage to this region than in the voyages which are now undertaken each year by tourists to the North Cape and Spitzbergen."

In conclusion, these northern lands hold distinctive conditions which are precious. Here is a field for a benevolent enterprise, with more surety of practical results than are to be had elsewhere. This field, reported on and indorsed by professional men and others who know whereof they speak, is worthy the attention of those who could begin such an undertaking.

INFANTILE PSEUDOLEUKEMIC ANEMIA.

J. GARNET HUNT, M.D.

Interne New York Postgraduate Hospital,
NEW YORK CITY.

This disease of infancy is one about which there has been a great deal of discussion among writers on diseases of the blood since von Jaksch, in 1889, first described the disease which now bears his name. Italian writers recognized and described peculiar forms of grave

¹ *American Medicine*, vol. vii, No. xvii, April 23, 1904. *Washington Medical Annals*, vol. iii, No. v, Nov., 1904.

² "Medical Affairs in the Heart of the Arctic," *The Journal A. M. A.*, 1905, vol. xiv, pp. 1564, 1647.

anemia in children as far back as 1880, which they placed in an intermediate position between leukemia and Hodgkin's disease. Some authorities, Ebstein, Fischl and Cabot, do not recognize it as a clinical entity, but classify all such cases as pernicious anemia, leukemia, or secondary anemia with leucocytosis.

This controversy arises primarily from the fact that in young children there is a tendency for the blood in all forms of severe anemia to retrogress to an embryonal form; added to this, there is a much more active response to chemotactic influences; and a general tendency of the spleen to become hypertrophied in all cachectic diseases of infancy. The lack of detailed laboratory and postmortem reports in the cases described by the early writers, together with the wide variations in their blood findings, have added to the confusion and made it almost impossible to agree on a classification. In recent years there have been very few cases reported. Glicknar, in 1898, described three cases which tally closely with the following one:*

Patient.—M. M., male, aged 15 months; one of twins; poor condition at birth, weight 4 pounds; had pertussis when 8 months old; twin brother died of marasmus; breast-fed 11 months; other foods, which were supplied by charitable institutions for a few weeks previous to admission, such as dextrinized barley and meat juices, were given irregularly. Parents extremely poor and ignorant; father alcoholic.

For the past month, the child had been gradually growing thinner, weaker, and more irritable. He was admitted to the Babies' Wards of the New York Postgraduate Hospital, May 29, 1905, weight 10 pounds 8 ounces, temperature 99.6, pulse 138, respiration 38. His general appearance was that of severe malnutrition, of the marasmic type, the anemia being a marked feature.

Examination.—(a) Head large, hair thin and dry, no bosses or craniotabes. Face showed marked loss of subcuticular fat, skin wrinkled and general wizened expression.

(b) Thorax was small; palpation and percussion negative; on auscultation no adventitious sounds were heard over either lung, and the breath sounds were of normal intensity, except over the upper lobes posteriorly, where the sounds were heard less distinctly. Apex beat was in fourth intercostal space, just outside the mammary line. Heart sounds regular, and of normal character.

(c) Abdomen was prominent; walls flaccid, due to loss of muscular tone; spleen was readily palpable, its anterior notched border extending two and one-half inches beyond the left costal margins. Lower border of liver was just palpable below the ribs.

(d) Extremities were very emaciated; muscles weak and flabby; epiphyseal cartilages not enlarged; feet and hands cold, indicating poor circulation.

(e) Glands in the axilla and groin were palpable, but soft and non-agglutinated.

Course of the Disease.—On admission the child was given the usual laxative, and placed on substitute feedings of dextrinized barley gruel, and beef juice. Later, cows' milk (modified) was added. The urine examination at this time gave the following results: Sp. gr. 1018; no albumin or sugar; urea 2 per cent, indican a trace; microscopically, a few epithelial elements.

Ten days after admission the patient developed symptoms of gastroenteritis. The stools became frequent and watery, of a greenish-yellow hue, and vomiting occurred, soon after taking food. The temperature, which till this time had been practically normal, suddenly rose to 104, with a corresponding increase in the pulse rate and respiration. These acute symptoms soon subsided; nevertheless, from this time on, the child failed steadily, in spite of everything that was done for him, the weekly weightings showing progressive losses of from two to eight ounces. At this time also the child developed a

very troublesome cough, which particularly disturbed his rest at night. Physical examination indicated slight dullness on percussion over the posterior aspect of both apices, with diminished breath sounds and increased vocal resonance.

The temperature curve showed daily variations of one to three degrees, the maximum being in the evenings until within a few days of his death, on July 17, during which period it remained either normal, or subnormal. A second urine examination made a few days before his death gave, sp. gr. 1022; albumin, moderate trace; sugar, none; urea, 2.2 per cent; indican, marked trace; microscopically, a few hyaline and finely granular casts.

The first blood examination was ordered on June 14, to eliminate, if possible, pneumonia or sepsis, as a cause of the sudden elevation of temperature that occurred at that period, and then it was that the blood dyscrasia underlying all these previously mentioned clinical manifestations, was first discovered. As a result, the child was given minimum doses of Fowler's solution, t. i. d., for two days, after which, on account of an exacerbation of bowel trouble, the drug was discontinued. It is worthy of note, however, that the following weekly weighing showed a gain of ten ounces. Three other examinations of the blood were made at intervals, the last one being but three days previous to death. For purposes of comparison the different blood findings are tabulated, as follows:

TABLE OF BLOOD FINDINGS.

	June 14.	June 23.	July 3.	July 14.
Hemoglobin (Dare's), per cent.	38	35	31	30
Erythrocytes,	3,120,000	2,920,000	2,740,000	2,720,000
Leucocytes,	14,400	18,000	19,540	16,200
Erythroblasts,	2,800	2,700	2,660	17,600
Color index,	603	593	563	549
<i>Differential count:</i>				
A.—of W. B. C.				
Polymorphonuclear, per cent.	18	20	36	21
Small mononuclear, per cent.	28	27	19	31
Large mononuclear, per cent.	42	41	28	35
Transitional, per cent.	1	1	1	1
Eosinophile, per cent.	2	3	6	3
Myelocytes, per cent.	9	8	10	9
	100	100	100	100
B.—of nucleated R. B. C.				
Normoblasts, per cent.	6	8	26	43
Megaloblasts, per cent.	94	92	74	57
	100	100	100	100

The above percentages of the different forms of white blood corpuscles were obtained by finding the relative frequency with which each of them occurred in a count of 500 or more leucocytes, in a stained slide-preparation. The number of nucleated red cells to the cubic millimeter was determined by first counting all the nucleated elements found in the Turek counting chamber, and then deducting the number that represented the percentage of erythroblasts as found in a differential count of both varieties of nucleated blood cells.

From a study of the table the following facts will be noted:

(1) A severe, thorough, not extreme, reduction in the red blood cells; (2) a constant, uniform, and well-marked leucocytosis, in which the mononuclears predominate; (3) a great number of nucleated erythrocytes, particularly of the megaloblastic variety. The tremendous increase of both varieties noted in the last count may be ascribed to an acute exacerbation of the blood changes preceding death; (4) a low color index; (5) constant presence of myelocytes neutrophilic, basophilic and eosinophilic.

There were considerable variations in both the size, and staining of the erythrocytes. Poikilocytosis was marked, and karyokinetic figures were not infrequent. The accompanying illustration graphically represents a composite picture of the cellular changes.

Postmortem Examination.—All the tissues and organs examined had one characteristic in common, extreme pallor and bloodlessness.

Spleen.—Greatly enlarged in all its dimensions, weight 91 gms., slaty-blue in color, very firm consistency. The cut surface did not bulge and the Malpighian corpuscles were indistinct. Microscopically the capsule showed a slight uniform thickening. The trabeculae were markedly hypertrophic,

* This case is reported by kind permission of Professor Callie, attending physician to Baby Wards, New York Post-Graduate Hospital, under whose care the patient was.

the fibrous elements being predominant; there were present, however, a few elongated, darkly stained nuclei, and a moderate amount of degenerated blood-coloring matter, between the fibers. The pulp reticulum was also greatly increased. In the pulp itself four changes were noted: (1) The presence of a large number of round cells, with oval nuclei, and a varying amount of protoplasm; (2) a great increase in eosinophilic cells, containing usually one or two dark-staining nuclei; (3) a deposit of degenerated, amorphous blood pigment in the intercellular spaces; (4) a great diminution in the usual number of erythrocytes. The Malpighian corpuscles did not appear to be affected to any appreciable degree.

The *Uterus*,—was slightly increased in size, and normal in consistency; acini markings were indistinct; cut surface was smooth and very pale. Microscopically there was no deposit of iron pigment in the liver cells; there were no collections

dominal organs—the intestines and pancreas—were not examined microscopically, as they showed no gross lesion.

Of the *thoracic viscera*, only the lungs were examined microscopically. The thymus was not enlarged. The heart was contracted, of normal size and consistency, but markedly anemic.

The *lungs*,—a strip of hypostatic congestion extended along the posterior aspect of both lungs, while at the apices there were small portions of non-aërated parenchyma. Microscopically, these portions of lung tissue were found to be areas of bronchopneumonia, with marked congestion of the small arteries and a desquamation of the alveolar-bronchial epithelium; the nucleated erythrocytes in the lumina of these vessels were very numerous. There was also a remarkable proliferation of the fibrous tissue in the trabeculae, and in the adventitia of the vessels, which extended into the alveolar framework. As in all other organs examined, there was noted a deposit of degenerated blood pigment in the intercellular spaces, especially in the congested areas. The pleura was slightly thickened over the sight of the pulmonary involvement, but showed no evidences of acute inflammatory changes.

Regarding the important causative factors in this disease, although much has been written of a speculative nature since von Jaksch's publication, we are still no nearer a solution of this problem. Rickets, chronic intestinal catarrh, syphilis and tuberculosis, have each played a part in certain of the cases reported, most commonly the first and second of these. An infectious origin was claimed by certain writers as early as 1880, but it has never gained wide acceptance.

The three conditions of the blood from which this disease must be differentiated are pernicious anemia, leukemia and secondary anemia with leucocytosis. The diagnosis rests on three factors (a) the clinical history, (b) morphology of the blood, (c) the pathologic changes in the viscera (Ewing).

Clinically, the points to be considered are the age of the patient, usually 1 to 4 years; the presence of rachitis or chronic intestinal catarrh, the enlarged spleen, the absence of any other assignable cause for leucocytosis, and the relatively favorable prognosis in this form of anemia.

In regard to the blood changes, the essential features are grave anemia, uniform and persistent leucocytosis, and lowered hemoglobin ratio. The erythrocytes are always markedly reduced in number, but seldom to the extent that occurs in pernicious anemia; the variation in size, shape and staining and the number of nucleated cells are marked, but not distinctive features in anemia infantum. The leucocytosis usually varies from 20,000 to 50,000, although much higher counts have been recorded. These latter cases, especially when associated with enlarged liver, must always be accepted with a great deal of hesitancy, unless the diagnosis be confirmed by the postmortem findings, being otherwise often indistinguishable from leukemia. In most of the cases in which differential counts have been made, the lymphocytes have predominated, and in some instances formed as high as 80 per cent. of the total number of white blood cells. The presence of myelocytes is a frequent though not absolutely essential feature; they do not, however, approach the proportions found in the myelogenous form of leukemia, the highest count recorded being 10 per cent., by Luzet.

As regards the tissue changes, their significance has not as yet been accurately determined. From an anatomic standpoint, however, they are sufficiently characteristic to justify the separate classification of these cases. The absence of iron deposits in the liver cells and of the characteristic lymphoid nodules in the vari-

Representation of the blood in infantile pseudoleukemic anemia, drawn from an eosin-hematoxylin preparation. 1. Myelocyte. 2. Eosinophilic myelocyte. 3. Megaloblast. 4. Chromatophilic megaloblast. 5. Karyokinetic megaloblast. 6. Normoblast. 7. Myelocytic hydrops of nucleus. 8. Megalocyte. 9. Large mononuclear leucocyte. 10. Small mononuclear leucocyte.

of round cells between them; a few eosinophile cells were present and degenerated hemoglobin was found in the intercellular spaces between the liver columns.

The *kidneys*, the capsule was non-adherent; cut surface was pale and cloudy. Microscopically there was a cloudy swelling of the cells in the glomeruli and convoluted tubules. On looking closely, brown, amorphous granules of blood pigment were noted in the perivascular spaces.

The *stomach*, was of normal size and texture. Mucosa, although very pale, showed no evidences of any hemorrhagic condition. Microscopically there was nothing of pathologic interest, except for the presence of a slight amount of amorphous pigment in the intercellular spaces. The other ab-

ous organs is quite sufficient to preclude the placing of them under the heads of either of the two forms of primary blood dyscrasia mentioned above—pernicious anemia or leukemia.

While considering differential diagnosis, attention is drawn to the great similarity in the general appearances and clinical manifestations of these cases, to the ordinary severer forms of malnutrition. So striking is this outward resemblance that it is not surprising that there may be no suspicion of the real trouble, previous to the examination of the blood. Hence, in my opinion, it is highly important, both from the standpoint of the child and in the interests of scientific medicine, that, whenever possible, a complete and systematic blood examination should be made in every obscure and obstinate case of malnutrition, particularly if the physical signs indicate enlargement of the spleen.

The prognosis depends largely on two factors—the early diagnosis and the ability to procure proper treatment. In neglected cases the outlook is grave indeed.

The treatment, as in nearly every other disease of childhood, resolves itself primarily into a question of improving the hygienic surroundings of the patient, and carefully regulating the diet to suit the condition of the stomach and intestines. There is, however, one drug—arsenic—which, if not a specific, has been recommended most highly by the different writers on this subject. It should be administered in the form of Fowler's solution, starting with a minimum dose and gradually increasing to the limit of toleration.

THE LOCALIZATION OF THE HIGHER PSYCHIC FUNCTIONS,

WITH SPECIAL REFERENCE TO THE PREFRONTAL LOBE.*

CHARLES K. MILLS, M.D.

Professor of Neurology in the University of Pennsylvania; Neurologist to the Philadelphia General Hospital.

AND

T. H. WEISENBURG, M.D.

Instructor in Neurology and Neuropathology in the University of Pennsylvania; Assistant Neurologist to the Philadelphia General Hospital.

PHILADELPHIA.

Cerebral localization had several epochs during the nineteenth century. At its dawn the views of Gall had awakened interest not only in the scientific world, but in all the European centers of population. Gall had boldly advanced the idea that the brain was not only subdivided into centers of special function, but that these were indicated on the outside of the head by peculiar prominences and conformations. An essential element of his phrenology was the existence of cranial salients, recognizable by the skilled fingers of the examiner, and constituting the ectal correlatives of ental physiologic centers in the brain substance. The bumps of the phrenologist represented gyres and subgyres, in which resided, as in the compartments of an elaborately arranged house, the habitants of the soul or mind.

Gall, who was a worker as well as theorizer, eventually lost himself in mazes of his own creation, but he will at least be remembered as one who fastened the eyes of the world on the truth that all parts of the brain do not act together for a single purpose, and that a single

part of the brain is not sufficient for all the functions of the mind.

For nearly three-quarters of a century the advances made in our knowledge of cerebral localization were limited. The one great discovery before 1870 was that of the existence of a center for speech in the hinder part of the left third frontal convolution—the center of Broca.

As the result of the impetus given by Hughlings Jackson, in his suggestion that certain small areas of the cerebral cortex were representative of particular movements, the researches of Hitzig and Fritsch, of Ferrier, Charcot and others were given to the world between 1870 and 1880, and the existence of a cortical motor zone with many subareas or centers was soon almost universally recognized. Before long, visual, auditory and other sensory phenomena were found to have their cortical representation.

For nearly a quarter of a century attention was concentrated on the discovery of separate cortical centers, until Flechsig (1893), through his embryologic researches, demonstrated the importance of recognizing not only primordial centers of sense and of movement, but also the existence of cerebral association areas concerned with intermediate and higher psychic functions. Since the period inaugurated by Flechsig, the subject has evolved in two directions: 1, In the direction of a more exact delimitation of areas and centers concerned with primary functions; 2, in that of the recognition of subdivisions of Flechsig's posterior association area, the concrete concept area or the concrete memory field. The visual and auditory subdivisions of this concrete memory field have in particular received some exact subdivision through clinicopathologic, morphologic, anatomic and physiologic research. The views of the authors in regard to cortical localization in general have been indicated in diagrammatic schemes published by one of us.¹ It will be observed in studying these schemes that not only are lower and higher areas of vision and audition indicated, but also special areas for cutaneous and muscular sensibility and stereognostic conception.

Each sensory zone has contiguous to it a motor area or center, the main motor region being that which is closely related topographically, as it is functionally, to the areas of cutaneous and muscular sensibility.

We shall not go into any detailed consideration of these zones, subareas and centers. This glance at the history and the present status of cerebral localization is given in order to lead up to the particular subject of the present paper, which is concerned with the centers of the highest psychic functions. We hold to the view that the highest mental faculties or functions have their material representation in the prefrontal lobes of the brain, and especially in the left prefrontal lobe. Our concern will be to give the general data and reasons for this belief, supplementing the paper with a report of a case of tumor of the left prefrontal lobe recently observed.

Gall and his followers made an elaborate subdivision of the faculties of the mind as understood in their time. One mistake made by them was that they did not recognize the essential difference between a fundamental faculty or function of the brain and certain cerebral side

* From the Department of Neurology and the Laboratory of Neuropathology, University of Pennsylvania.

attributes or epiphenomena. The ability to attend, to will, to judge, to compare, to reason and to exercise the imagination are fundamental psychic functions; the exhibition by an individual of pride, of vanity, of friendship, of combativeness, of piety, of filial love, of sexual passion or similar propensities, is not due to the operation of any single mental faculty or function. The former are the vocations, the latter the avocations of the mind. The former are represented by special centers associated by special tracts; the latter result from the action of one or several or many of the regions of the brain.

The evidence afforded by studies in human and comparative morphology and anatomy of the cerebral surface in favor of the view that the prefrontal lobe, and especially the left prefrontal lobe, is the seat of the highest mental faculties, is of much value. Already a considerable number of the brains of notable men presenting special fissural and gyral arrangement and development of the prefrontal region indicative of high or unusual endowment have been put on record. Reference need only be made to the classical cases of Gauss, Helmholtz and Grote and to the more recent studies of E. A. Spitzka on the brains of the two Seguins, Cope, Harrison Allen, Major Powell and others. If the anatomic and morphologic characteristics of such brains are placed side by side with those of criminals, paranoiacs, negroes and other human beings of low individual or racial development (as studied by Dr. Mills and others), the psychophysiologic importance of the prefrontal region becomes apparent. It might be remarked in passing that morphologic and anatomic studies do not always seem to give to the left prefrontal lobe the preponderance in higher mentality attributed to it by some. Spitzka, for instance, found in the brain of Major Powell a preponderant development of the mesal surface of the right frontal lobe. In studies of this kind a comparison should always carefully be made between the fissural and gyral characteristics of the prefrontal and parieto-temporo-occipital areas. A superior development of the latter is not always accompanied by an equally superior pattern of the former. In rare cases the former may largely outclass the latter.

Morphologic studies of the brains of imbeciles, such as have been made by Wilmarth and others, are corroborative of the view of the higher psychic functions of the prefrontal region. These brains are, as a rule, characterized by unusual simplicity in fissural and gyral arrangement.

The embryologic researches of Flechsig and the histologic investigations of Campbell show, among other things, the absence of projection cells and fibers in this portion of the brain. The latter speaks of the prefrontal region as the very last pallium to appear in the progress of phylogenesis. We may accept this statement and regard it as in accord with our views of the functions of this part of the brain. The last and the least organized portion of the nervous system is the most highly organized and most specially endowed.

Gross and microscopic examinations of the brains of general paresics support in some degree the thesis that the prefrontal portion of the cerebrum is the seat of its highest functions. It is probable that careful pathologic investigation of the brains in cases of dementia præcox will afford similar evidence.

Presuming that the prefrontal lobe is especially concerned with the highest intellectual functions, the question arises whether or not this region is divided into sub-

areas and centers is one which is naturally suggested. In such a study we have not to guide us comparatively coarse and easily differentiated phenomena-like movements and disorders of cutaneous sensibility, or of the special senses.

The higher psychic faculties themselves are indeed usually so interblended in expression as to make a study of their relative maintenance, loss or increase in particular individuals, a matter requiring trained powers of observation and analysis, such as are not often possessed, or at least exercised, by those recording cases of disease, arrest of development or unusual endowment. It is possible that the clue to the subdivisions of the highest psychic region may be found by a consideration of the position and relations of the centers of known functions contiguous to the prefrontal lobe. Intermediate between this lobe and the area recognized as motor are situated centers concerned with speech and with writing. Broca's center is situated just anterior to the centers for articulation, enunciation and phonation, the subdivisions of the so-called face area. Speech is the chief instrument employed in reasoning and the psychic centers of ratiocination should be topographically closely related in position to the center of Broca. Writing administers to exactness in thinking and the centers of comparison and judgment may have their highest development contiguous to the graphic center. While in the main the motor centers, for the face, arm, trunk and leg are limited to the precentral convolution, the centers for movements of the head and eyes, and especially for movements of the eyes alone, are thrust toward and into the prefrontal lobe. Attention and volition have their most marked physical expression through vision and position of the head, and if centers for these mental faculties or processes are differentiated their most probable situation is in parts contiguous to centers for movements of the eyes and head.

One of the greatest difficulties of proving the localization of the highest intellectual processes has arisen from the fact that physicians, even those trained in neurology and psychiatry, frequently fail to note the mental symptoms carefully or describe them in such an uncertain manner as to make the records of little value. It is surprising, considering the richness and profusion of the clinicopathologic contributions to cerebral localization during the last two or three decades, how few of these have any notable value regarding the higher psychic functions. In our own language, the contributions of Phelps² are of especial value. An elaborate study of personal and other cases is made by Phelps, who arrives at the conclusion that the left prefrontal lobe is the seat of the highest mental processes. He says:

The large number of cases cited, with the analysis of their symptoms and lesions, are probably sufficient in themselves to form a basis for conclusions. They represent the personal observation and record of 800 cases of intracranial traumatism, of which more than 300 were subjected to either operative or postmortem inspection. Excluding those cases in which death had been preceded by primary and permanent unconsciousness, they were all germane to the present inquiry as showing either the presence of left frontal lesion where mental symptoms had been noted, or the absence of such symptoms where the lesion was situated in any other region of the brain.

Besides the series of traumatic cases compiled by Phelps, other collections of cases of prefrontal lesion have from time to time been published, as well as a con-

2. Phelps, Charles, New York Med. Jour., Nov. 10, 1894, to Jan. 12, 1895; "Traumatic Injuries of the Brain," etc., New York, 1897, 1900; Amer. Jour. of the Med. Sci., April, 1902.

siderable number of isolated cases either due to disease or injury. Some of these, like the crow-bar case, have so often been recalled that they are now well known to the profession at large. The inferences drawn from both the individual cases and the compilations have been conflicting, some holding that they prove nothing as regards the functions of this portion of the brain or only indicate that it is physiologically negative; on the other hand, a very considerable number of cases of lesions situated elsewhere than in the prefrontal lobes and giving symptoms indicative of the involvement of the higher psychic faculties, have been recorded. We believe, however, that the comparatively conflicting cases can be satisfactorily explained. In many instances the individuals whose cases are reported have been of a relatively low intellectual status, and as already intimated, physicians in general are not well equipped to put on record psychic symptoms in detail. Frequently the mental condition and symptoms, which are due to the irritative or distant effects of a cerebral lesion, especially when this is a tumor are not taken into account by the reporter. We believe that if each case of prefrontal disease and especially destructive disease of the left prefrontal lobe, is carefully studied it will be found that mental symptoms of a special character can always be recognized, and that these will be in the domain of the higher psychic activities.

E. Müller, in 1902, published three exhaustive papers on the frontal lobe, his chief object in these contributions being to present the question of the psychic functions of this portion of the brain. His frontal lobe practically coincides with the prefrontal lobe of the writer's—that portion of the brain in advance of the generally accepted motor region and of the graphic and motor speech centers. While he gives details of only one case of his own, he has collected from the literature no less than 164 cases of lesion or disturbance of this portion of the brain, these including tumors, concussion, injuries and other lesions.³

We have only space in this paper to give his most important conclusions, with brief references to one or two points of special interest in his studies, which were not only clinicopathologic, but included to some extent a consideration of facts of physiology, morphology and psychiatry. He asserts, as the result of his studies, that tumors of the frontal lobe need not always cause disturbance of the higher psychic functions, but admits that they do this frequently. He holds that psychic disorders of various sort may result from tumors situated in any portion of the brain. He believes, further, that the disorders of the higher intellectual functions which are so frequently noted in prefrontal lesions, are due, especially in the case of tumors, to the fact that these being in a region latent as regards physical symptoms, the cases remain a longer time under observation, and hence the mental disorders are more frequently studied. He contends that psychic symptoms in cases of brain tumor do not occur alone, but always in association with other symptoms. He does not believe that prefrontal tumors necessarily produce psychic symptoms of a special kind. He does not believe that morbid wittiness (*Witzelsucht*), which has been advanced by some German writers as a symptom especially depending on disease of the frontal lobes, is to be attributed to lesion or disturbance of this region, his analysis of cases seeming to show that it may occur from lesions in various parts of the brain. In 22

cases of tumors or other lesions involving both frontal lobes cited by him, this symptom was absent. We might remark in passing that although we have seen many cases of brain tumor, a number reaching into the hundreds, this symptom has been extremely rare in our experience.

Schuster,⁴ also in 1902, contributed a paper based on a study of no less than 775 cases of tumor. He found from his analysis that tumors of the callosum always gave mental symptoms; next in order came tumors of the frontal lobes, which gave the same symptoms in 80 per cent. of the cases; tumors of the temporal, parietal and occipital lobes gave psychic disorders in from 54 to 66 per cent., while tumors of the base gave these symptoms in only 25 per cent., and cerebellar tumors in 35 per cent.

Both Müller and Schuster agree that in the majority of instances the prevailing psychic disorders are disturbances of the sensorium, of orientation and of consciousness, the last showing themselves chiefly in hebetude or stupor.

Von Monakow,⁵ in a paper published in 1904, refers to the statistics of Müller, Schuster and others, and discusses the subject from a physiologic point of view, concluding that the physiologic evidence is insufficient to prove that the psychic functions are especially located in the prefrontal portion of the brain. He believes that psychic disturbance may occur from tumors situated anywhere in the cranial cavity. He also agrees with Müller and Schuster that tumors of the prefrontal area need not cause disturbance of the higher psychic functions.

The papers of Müller, Schuster and Von Monakow, like many others of less elaboration written on this subject, are defective in their discussion of the subject, in that clear distinctions are not made as to the character of the psychic disturbances caused by tumors located in various parts of the brain. The chief sources of fallacy would seem to be (1) that sufficient stress is not laid on the fact that owing to the painful and exhausting character of brain tumors, mental disturbances in the broad sense may occur because of the irritation and exhaustion produced by these lesions; (2) it is not clearly brought out that tumors of the posterior association area or concrete memory field of the brain will necessarily cause some disturbances of mentality, especially those in the domain of orientation and in the sensorial field; (3) that tumors anywhere situated may cause mental disorders simply through the disturbance or impairment of association which must result; (4) sufficiently close attention is not paid to the particular point that the psychic disorders caused by prefrontal tumors are especially those of the higher intellectual functions, and that in many of the cases studied the normal mental status of the individual is not properly taken into account; and (5) the fact is not recognized that in tumors situated in one of the prefrontal regions, especially in the right, the individual's intellectual faculties may be largely preserved because of the integrity of the corresponding region of the other side.

We can only arrive at satisfactory conclusions by the closest and most thorough clinicopathologic or clinicosurgical studies of prefrontal tumors.

The following case recently observed is one of unusual interest because of the strict limitation of the lesion to the prefrontal lobe as defined in this paper.

namely, that part of the cerebral hemisphere which is situated laterally and mesally cephalad of a line drawn vertically through the pre-Sylvian fissure, and on the inferior surface of the brain is cephalad of the Sylvian fossa:

X. Y., 71 years old, was a well-known physician who had, up to within a few months of his death, pursued his profession successfully, at the same time taking a moderate part in the management of other business interests.

About two months before his death he was first seen by Dr. Mills, who had been consulted by his son regarding him some weeks previously. His symptoms at this time were all mental, being chiefly exhibited in defects of memory and judgment.

A careful examination was not made at this time, as it was the desire of his family not to have him recognize the fact that his condition was being made the subject of investigation. He had not any paralytic or sensory symptoms, however, and, so far as could be determined by the examination that was made, none in the domain of his special senses. Unfortunately, an ophthalmoscopic examination was not made. His symptoms appeared at the time to correspond to those frequently seen in cases of cerebral arteriosclerosis.

He had frequently put his hand to the left side of his head, as if suffering from uncomfortable sensations, but he did not call attention to any pain or distress in his head by speaking of it.

Shortly after this he was noticed to have a shuffling gait, and later he was unable to convey food to his mouth with any certainty. Soon after he began to have muscular tremors in

physician, he having at this period taken charge of his son's practice during the latter's absence on a vacation.

In the summer and fall of 1904 it was observed that he was no longer attentive to the care of his house, he having formerly been particular in this respect. At the table he became more careless, as in carving and carrying food to his mouth. He was indifferent as to what occurred, as when he dropped food on the table or in his lap.

His loss of memory seemed to develop rather suddenly about Dec. 1, 1904. Memory for recent events failed first; he soon forgot his recent patients and would ride about hunting those he had not seen for years. He even made charges in his books to patients who had been dead for years. He never seemed to lose himself, and in his drives about the country within a month of his death he always seemed to know where he was.

A gradual loss of judgment and comparison had occurred after the fall of 1904. When, for instance, his son consulted him about some business matters which he had known all about better than any one else he answered that he did not know and that so and so had better be consulted. A slightly

Fig. 1.—Photograph showing the tumor as viewed in front, laterally and at the base. *a*, upper limit of the tumor; *b*, recent hemorrhage; *c*, the line of the longitudinal section through the cerebrum.

his hands and legs, much like those seen in paralysis agitans. At first they were on the left side only, but toward the end involved the right side also. They were at first partially under control, and by an effort of will he could stop them; later he could not, and they occurred also during sleep.

About six weeks before his death he had occasional turns of vomiting for about a week; a week later one or two more. These were the only attacks of vomiting he had during the whole course of his disease.

About two weeks before his death the patient suddenly became unconscious, this condition lasting for three days. He then rallied and could be aroused during part of the day and answer questions. The comatose condition gradually returned and he died very quietly with no convulsions or any unusual symptoms.

At our request the patient's son, an unusually observant and well-equipped physician, sent us a description of his symptoms from the time when they were first noted by members of his family. The patient died April 19, 1905. Attention was not particularly directed to any evidence of mental failure until December, 1904, although his son stated that on looking back he felt sure it began much earlier. In the summer of 1904 he seemed to have lost, to some extent, his grasp as a

delusional state developed. This was mostly with reference to medical work. He had an idea that he was very busy, that he was sent for to various places, and he would hurry around to do what he thought was his work. He would stop at all sorts of places, hunting the persons who were sick. In the evening he would try to tell where he had been, but got hopelessly confused. Once he thought for a number of evenings in succession that he had theater tickets and must get ready to go, although scarcely in his life had he been to the theater. On account of his wife's deafness he was in the habit of giving her verbal reports of sermons. During the few months preceding the development of marked symptoms she noticed his accounts were becoming confused, and that he could not give a clear idea of what was said.

Another quite early symptom was change in disposition. He would sit at meals without saying anything, and became exceedingly mild and gentle. His ordinary greeting became unnaturally cordial.

No marked change occurred in writing until about December, 1904, when it became decidedly more careless. Spelling was not affected, although he frequently used a wrong word even a month or two earlier. During December his letters became confused and careless. He would start with an idea and then

become bewildered, and would repeat the same words and phrases several times.

The necropsy was made about twenty-four hours after death. As the body had been carefully injected with formalin, on removing the calvarium the brain in general was found to be in an unusually good state of preservation. On attempting to remove the brain from the skull the anterior pole of the left hemisphere was found to be adherent to the skull, necessitating careful dissection of the adhesions at this point. A small quantity of blood was seen oozing from the left Sylvian fissure at its anterior inferior extremity. It was evident while the brain was still in position that an abnormal mass was present in the left prefrontal region, the brain substance, the membranes and the lesion present not being separable.

The lesion was found to be a prefrontal tumor, which was fleshy in color, hard in consistence and well-defined from the surrounding tissue. Studied from its lateral aspect, the tumor was absolutely prefrontal, occupying the anterior third of the first frontal gyrus, the anterior fourth of the second and slightly less of the third. It occupied practically the entire orbital surface and on the mesal aspect the entire area cephalad and ventral of the knee of the callosum; it also involved the callosum itself, the mass projecting toward the other hemisphere. A good idea of the lateral and the anterior position of the tumor is given by the photograph (Fig. 1).

A horizontal section of the entire brain made just below the level of the callosum showed that the growth involved the entire subcortex and cortex of the first and second frontal gyres, but only the orbital portion of the cortex of the third frontal, laterally the outskirts of the growth only reaching to within three-eighths of an inch of the cortex. The tumor extended backward so as to involve the anterior extremities of the caudatum and internal capsule, as shown in the photograph (Fig. 2).

Caudad of the tumor in the Sylvian fissure, a fresh hemorrhage was found, this having destroyed in large part the insula. The nerve cells of the cortex, as shown by the Betz cells in the paracentral lobule, were in a fair state of preservation. Here and there was found a diseased cell, but these were not numerous. In these cells the nuclei were found in the periphery and the chromophilic elements stained diffusely. The pia was of normal thickness. The arteries throughout the entire brain were markedly sclerotic; in fact, they were so much so that at the base of the brain the anterior cerebral arteries pressed upon the optic chiasm, causing the optic nerve on each side to assume a semi-lunar shape. On cross-section the optic nerves showed a slight amount of degeneration. Sections taken from different parts of the cortex and from the oblongata did not show any alterations.

DISCUSSION.

DR. H. A. TOMLINSON, St. Peter, Minn., said that from his own experience in the study of the brains of the defective and demented he could confirm the conclusions presented in the paper. In the defective the most constant variation has been toward imperfect development of the frontal convolutions and the tendency toward perpendicular fissuration, while in the demented there is the shrinkage of the frontal lobes antero-posteriorly and the atrophy of the frontal lobes in front of the precentral fissure. It seems to him that the preponderance of the left prefrontal lobe in the intellectual functions is due to the same causes that influence the motor convolutions. The larger number of impulses that have to be related, inhibited or directed come from the left side of the brain, and especially from the centers of expression on that side. In left-handed persons the converse of this relation will probably be found to be very nearly constant, but not entirely so, because left-handed people are apt to be ambidextrous. Microscopically, the most marked degenerative changes are found in these same areas in dementia and in the associated areas that have to do with expression. His experience has furnished him with what seems to him to be ample negative proof of the truth of Dr. Mills' conclusions.

DR. WILLIAM HOUSE, Portland, Ore., said that these cases are comparatively frequent and he is unwilling to believe that Dr. Mills' recent observations were limited to the one very interesting case presented. Within the past year Dr. House has

seen not less than three cases of lesion of the prefrontal lobes. The first was a bullet wound which had punctured the right side of the brain about the junction of the second and third convolutions, passing through to the opposite occipital region and destroying a considerable area of the frontal cortex. The man lived eighteen months without exhibiting any symptoms, mental or physical, traceable to the wound. This case tends to oppose the contention of the authors of the paper. At the same time in another case in which he was unable to locate the growth during life, although limiting it to the right side, the chief somatic symptoms were weakness of the left side of the body, with increased left patellar reflex. Cerebration was slow and confused, and, in addition, there was loss of expression on the right side of the face, which when at rest presented a singularly blank appearance. The lesion proved to be a cyst of the right prefrontal lobe, and in presenting the specimen before the local society Dr. House called special attention to this evidence of psychic involvement, as it seemed to him that it should have been valuable in localizing the growth. In the third case, the necropsy revealed a large, probably carcinomatous tumor of the left prefrontal lobe. The symptoms included marked mental disturbance, loss of memory, slow cerebration, and confusion. Curiously enough, there seemed at times to be loss of hearing, and at other times marked acuteness, so much so that the patient could hear a whispered conversation in the next room, which he would recall and repeat twenty-four hours later. Dr. House also mentioned a fourth case, seen eight years ago at the Manhattan State Hospital, New York City, in a negro. The most marked mental symptom was a tendency to use large and often meaningless words, which may have been due, in part, to racial predilection. The diagnosis was paresis. The postmortem revealed a huge sarcoma, practically replacing both frontal lobes. Dr. House has seen fifty-four necropsies in paresis and has uniformly observed that in those cases which were markedly of the mental, rather than of the tabetic type, the pathologic process was always most pronounced in the frontal regions. It seems to him there can be no question of the importance of the frontal or prefrontal regions in the performance of the higher psychic functions, but he is at a loss to give a reason why involvement of the right prefrontal lobe, as noted in one of his cases, was accompanied by unusual mental symptoms, while an equally great involvement in another case was accompanied by none at all. He is convinced that careful study of these cases in time must yield definite information whereby neurologists will be able to distinguish lesions of the frontal lobes from those in the other brain regions. In reply to a question Dr. House said that in the case in which the face was involved there was neither a muscular nor an emotional paralysis in the ordinary sense of that word. The impression of blankness was present only when the face was completely at rest and disappeared when the man smiled or moved the muscles of the face.

DELAYED CHLOROFORM POISONING AND ALLIED CONDITIONS.

A NOTE ON THE CAUSE OF THE ANATOMIC AND CLINICAL CHANGES OBSERVED.*

II. GIDEON WELLS, M.D.

Department of Pathology, University of Chicago.

CHICAGO.

During the past two years surgeons have been aroused to the importance and frequency of delayed chloroform poisoning, and the literature of the subject has received a number of important additions. This has been so thoroughly discussed in the recent article by Bevan and Favill¹ that it is unnecessary to go into the details of the matter here, beyond mentioning a few of the salient features. The condition rarely results from other narcotics, but follows chloroform narcosis in probably no insignificant proportion, if we include all the non-fatal

* Presented before the Chicago Pathological Society.

1. JOURNAL A. M. A., 1905, xiv, pp. 691 and 754.

intoxications following operations under chloroform. A period of 10 to 150 hours elapses between the time of anesthesia and the appearance of the symptoms, generally between twenty-four and forty-eight hours. The symptoms are those of a profound toxemia, and in the urine are found organic acids and sometimes amido acids (leucin and tyrosin). At autopsy the anatomical changes are striking, most prominent being degenerative changes in the liver, these changes consisting of vacuolization, swelling, fatty changes within the cells, often much necrosis with evidences of absorption of the necrotic cells. The other parenchymatous organs share in these changes to varying degree, the kidneys usually standing next to the liver in amount of degeneration.

The manner in which chloroform brings about these changes has been one of the many problems of this subject. Are toxic substances that injure the liver and kidney generated elsewhere, or are toxic substances produced in the liver by its disintegration, which then poison the more vital organs? Is it an "acid intoxication" by the organic acids found in the urine, such as occurs in diabetic coma, or are these acids of merely secondary importance? What is the relation of chloroform poisoning to the numerous other conditions that resemble it closely both clinically and anatomically; namely, acute yellow atrophy, phosphorus poisoning, puerperal eclampsia, and many septicemias?

Through recent studies of the chemistry and biology of the cell we have learned certain facts, which, I believe, give us a clear insight into the essential changes underlying the group of toxic disorders above mentioned, and in none of them is the application more direct and clear than in chloroform poisoning. As the facts already at hand seem sufficient to furnish the necessary data for the hypothesis about to be advanced, I venture to state it without at present producing any personally-acquired experimental proof.

Every tissue cell contains a number of enzymes, by the action of which a large proportion of its metabolic processes are carried on. There are enzymes that bring about oxidations; enzymes that maintain the equilibrium between glycogen and sugar; lipase which splits fats and probably also synthesizes them, and also ferments which split up proteids much as trypsin does, although with certain minor differences. The above enzymes we know are in the cells; there are others known that are not so thoroughly studied, and probably there are still many others that are yet to be distinguished. The sum of the action of these enzymes, with perhaps the addition of certain simple chemical reactions between the substances they produce, constitutes the metabolic activity of the cell. If any one set of these actions is prevented the metabolic activity is greatly altered, perhaps with serious consequences.

We know, for example, that when the cell does not receive food, and therefore can not meet its splitting processes by synthesis of new tissue elements, the result is a splitting of the cell structure by its own ferments, *e. g.*, bacteria placed in distilled water undergo self-digestion, or autolysis. Similarly, if we stop in any other way the synthetic processes and still leave the proteid-splitting enzymes in an active condition, these enzymes will digest the cells. Hence if we were to poison the cells with a substance that stopped all the other life processes except the autolytic action, the cell corpses would be disintegrated by their own enzymes.

Now, chloroform happens to be, *par excellence*, just such a selective poison. It is a "protoplasmic poison," and may use the term, which does not to any extent im-

pede the action of the autolytic enzymes. If we add chloroform to a culture of bacteria the bacterial cells are killed, in that they are unable to multiply or to move about or to take up food and grow, but the proteolytic enzymes within them are still active and unimpaired, and these continue their proteid-splitting action. During life this proteolysis is being met constantly by synthesis, so that the changes balance one another; under chloroform the synthesis ceases while the proteolysis goes on, hence the process is all in one direction and the cell digests itself until its structure is destroyed and its proteids have been broken up into simple nitrogenous substances, such as leucin, tyrosin and ammonia compounds. Just the same thing happens if, instead of bacteria, we have under chloroform a piece of liver tissue, or an emulsion of liver cells; synthesis is impossible because there is no nutriment brought to the cells, and proteolysis goes on, the liver-cell proteids being digested into simple soluble substances.

In chloroform poisoning the process, I believe, is exactly the same. Chloroform is a protoplasmic poison, killing bacteria and unicellular animal organisms when in sufficient strength, merely inhibiting their activities when not concentrated. Its poisonous action is perhaps largely independent of its anesthetic property, which latter seems to be related more to its solvent effect on the abundant lecithin and cholesterol content of the nervous tissues. If the chloroform content of the blood is sufficient certain of the cells are poisoned to such an extent that their synthetic activities cease, while proteolysis goes on. The cells then undergo disintegrative changes as a result, and the products of this disintegration, which are to a greater or less degree poisonous, enter the circulation. Added to these are the toxic substances that accumulate because of the impaired function of the degenerated liver and kidney.

Just what elements of the cell are selectively inhibited or destroyed by the chloroform cannot be definitely decided on the evidence at hand, but I believe that the oxidative ferments are chiefly involved. If the oxidases in a cell were destroyed or inhibited we should expect to get just the changes that we observe in chloroform poisoning. The lipase would act without the normal balancing by oxidative destruction of fatty acid and glycerin, and so we should expect fatty changes, which are prominent features of chloroform poisoning. Synthetic changes seem largely to depend on oxidations and the correlated reductions, hence they would cease; the splitting of proteids would not be balanced by synthesis, and autolysis would occur. Oxidation of products of splitting would cease, and we should look for organic acids to appear in the urine, as is the case in chloroform poisoning.²

The corroborative evidence of the autolytic nature of chloroform poisoning is abundant. First and foremost is its close relation to acute yellow atrophy of the liver and acute phosphorus poisoning, in both of which, as Salkowski, Jacoby and others have shown, most of the changes in the liver are due to autolysis. The only specimens of postoperative chloroform poisoning that I have studied, a typical case since reported by Bayard Holmes,³ presented such a striking resemblance to acute yellow atrophy that the possibility of this diagnosis was considered for some time. In chloroform poisoning leucin and tyrosin have frequently been found in the urine,

2. Although some experimental investigation of the effects of poisons on oxidizing ferments has been attempted, the means at hand for measuring the activity of these ferments are too unreliable to permit of any definite conclusions.

3. Holmes: "Appendicitis," 1904, p. 214.

the cases then usually being reported as "acute yellow atrophy following operation," and these amido acids are undoubtedly the product of autolysis of the liver. If the urine had been examined more often chemically, instead of merely microscopically, there is little question that these and other amido acids would have been found quite constantly, as they are in acute yellow atrophy and phosphorus poisoning. Furthermore, in a case of chloroform poisoning resembling clinically acute yellow atrophy, Taylor⁴ found 4 grams of leucin, 2.2 grams of tyrosin and 2.3 grams of arginin (nitrate) in the liver.

The appearance of organic acids in the blood and urine in chloroform poisoning, which is so prominent that some cases have been reported as "acid intoxication following chloroform anesthesia," agrees fully with our hypothesis, for Magnus-Levy⁵ has found that such acids are constantly produced in livers that undergo autolysis outside the body under chloroform or other similar antiseptics. Their appearance is probably due to lack of oxidation, which under normal conditions of metabolism destroys them. Since Wiener⁶ has shown that autolysis occurs much more rapidly when the reaction is slightly acid than when it is neutral or alkaline, the presence of these acids is probably an important factor in the autolysis of the liver cells in which they are formed.

The relative harmlessness of ether agrees also with relatively slight poisonous properties; its anesthetic property is, as with chloroform, probably related to its solvent effect on the lipoids of the nervous tissues.

The predisposing causes of chloroform poisoning, as given by Bevan and Favill, also point to reduced oxidation as a prominent factor; e. g., diabetes, hemorrhage, wasting diseases, etc. The preventive influence that oxygen is supposed to exert is also referable to the same condition.

That children seem more often affected, "the younger the more susceptible," may be correlated with Schlesinger's⁷ observation that the autolytic power of the liver is greatest in young children.

Presumably the liver is most affected because it is the site of the most active autolysis and oxidative processes of the body.

The latent period between the time of the administration of the chloroform and the onset of the symptoms agrees with numerous observations to the effect that there is a latent period between the time an organ is removed from the body and the beginning of its autolysis, to which must be added the time required for the accumulation of toxic materials in sufficient quantity to cause symptoms.

SUMMARY.

Chloroform poisoning, in common with a number of closely-related conditions characterized by intoxication and marked changes in the liver (acute yellow atrophy, phosphorus poisoning, certain septicemias, and some cases of puerperal eclampsia) probably all depend on the effect on the liver of poisons that destroy the synthetic functions of the liver cells without destroying their autolytic ferments. Autolysis of the liver cells follows, with resulting alterations in the liver structure, and the appearance of products of autolysis (amido acids and various other organic acids) in the blood and urine. It is probable that in chloroform and in phosphorus poisoning, at least, it is the oxidizing enzymes that are particularly involved, accounting for the marked fatty changes that are present in these conditions.

CHORIONEPITHELIOMATOUS PROLIFERATIONS IN TERATOMATA.

ESPECIALLY IN THOSE OF THE TESTICLE; WITH THREE NEW CASES.*

ROBERT T. FRANK, A.M., M.D.

NEW YORK.

(Continued from page 256.)

3. HYDATIDIFORM PROLIFERATIONS IN TERATOMATA.

CASES IN THE MALE.

The preceding cases, many of them consisting of testicle tumors in which chorionepitheliomatous proliferation with teratomatous elements are demonstrable, are sufficiently numerous, similar and well authenticated to be accepted as a distinct and recognized variety of tumor. Schlagenhauser has, in addition, described what he considers a modification of these neoplasms, which bear a similar relation to chorionepithelioma of the testicle that hydatid moles bear to chorionepithelioma of the uterus. This author has personally reviewed the case reported by Karl Breus⁷² in 1878, and re-examined the material, also collecting five cases from the literature. All these cases have certain features in common. A primary testicle tumor is present in all; in most of them the testicle tumor is evidently a teratoma; in one only (Breus' case) do parts of the metastases resemble chorionepitheliomatous tissue. In all, metastatic extension into the large veins has taken place, usually reaching as far as the heart. The intravascular growths show, macroscopically at least, a striking resemblance to hydatid mole. If this resemblance is to be accepted as more than a merely superficial similarity, the microscopic findings must coincide with the picture seen in hydatidiform degeneration of the chorion, particularly in regard to the appearance and behavior of the ectodermic covering. In order to discuss this question, which has certain important theoretic features, a review of these cases is necessary, but as both Schlagenhauser and Risel give a full review and no new cases have been added, a condensed account will suffice.

Although not the first in point of time, it is well to consider Breus⁷² case, as reviewed by Schlagenhauser, before the others.

The autopsy showed a large testicle tumor in a man of 40. The tumor in addition to sarcomatous and carcinomatous portions contained cysts of diverse structure. The cord had attained the size of a thumb. Its dilated varicose veins were filled with narrow strands which could be traced into the internal spermatic vein and from it into the inferior vena, where the strand was 1.5 cm. in diameter, and had numerous club-shaped appendages.

In the lungs many large and small metastases were noted, the new growths being composed chiefly of syncytial forms with occasional scattered Langhans cells. According to Schlagenhauser the nodules should be regarded as villous emboli. Small branches of the pulmonary artery contained thrombi similar to those to be described below. In the left auricle, starting from the fossa ovalis, was a slimy, grapelike vegetation comparable to an hydatid growth. The small transparent masses had a more opaque center. In the right heart a similar picture was noted, but here the mass was directly continuous with a strand of the thickness of a finger, projecting into the inferior vena and forming a skein which filled the entire chamber and projected through the open foramen and into the left heart. The intravascular growths as-

* From the Department of Pathology of the College of Physicians and Surgeons, Columbia University.

sumed a complicated glove-like form composed of myxomatous and fibrous tissue covered by an epithelium which resembled both the Langhans and syncytial type. Within the grape were cysts clothed with cubical and cylindrical epithelium.

His conclusions are:

1. The primary tumor is a teratoma.
2. The grape-like vegetations are in part equal histologically to an hydatid mole.
3. The lung metastases are the result of villous emboli, and where the epithelial covering has proliferated, a chorionepitheliomatous tissue has been formed.

Summing up, he considers this case and the four others yet to be discussed as teratomata in which an hydatid-like proliferation within the vessel has taken place because the fetal membranes or their rudiments have undergone an intravascular hydatidiform degeneration. To account for this change occurring not in the primary but only in the intravascular portions of the growth, Schlagenhauser assumes that the ectodermal elements are here in a physiologically favorable condition, as, in a normal pregnancy, the fetal ectoderm physiologically has the property of invading the blood vessels. In the blood spaces the syncytial masses predominate, for it is their chief function to supply nourishment to the rest of the cells by osmotic processes.

Waldeyer¹⁷ reported his case as a myxo-chondro-sarcoma. In the spermatic cord hyaline, worm-like structures, attached by pedicles to the vessel walls, occupied the veins. The covering epithelium of these "hydatids" was continuous with that of the vessel walls and in spots was "heaped up" as if to form new pedicles.

Silberstein's¹⁸ case showed intravascular structures similar to those in the case of Schlagenhauser. The myxomatous groundwork of the grapelike formations contained cysts lined with epithelium. The testicle tumor probably was a teratoma.

The testicle tumor described by Kanchack and Pigg¹⁹ was evidently teratomatous. The enormous glandular metastases contained many cysts. In the great venous trunks and heart the hydatid-like growths were composed of fairly firm fibrous tissue and enclosed epithelial lined cysts.

MacCallum,²⁰ according to Risel²⁰ (p. 135), no longer regards the tumor he reported a lymph-endothelioma of the testis. The primary tumor may possibly belong among teratomata with very unequal development of the fetal layers. The widely distributed intravascular growths (re-examined by Risel) show a myxomatous groundwork, a cellular covering, continuous with that of the vessels, and cystic structures within the grape. Nowhere is chorionepitheliomatous tissue in evidence.

DISCUSSION BASED ON THE PRECEDING CASES.

Of all the cases, Breus-Schlagenhauser's should be most seriously considered. More important than the main intravascular growths are the small villous thrombi from which he directly traces chorionepitheliomatous nodules. If these findings are accepted, they would correspond exactly to the pictures seen in the metastases of a malignant hydatid mole. Risel²⁰ (page 132) objects to a genetic or even morphologic identity with these structures, claiming—undoubtedly with justice—that simple myxomata (two cases of Marchand) can assume hydatid-like forms within the large blood vessels through purely mechanical causes; but this fact would not necessarily exclude the possible occurrence of true hydatids under similar conditions. A stronger argument against the claims of Schlagenhauser is the presence of minute cysts, and not sharply circumscribed cell complexes, within the grape-like masses, and also the fibrous, more often than myxomatous, stroma, which

lends weight to the assumption that these intravascular metastases have no greater specific significance than the teratomatous metastases in Steiner's or Hansemann's cases. Schlagenhauser represents the epithelium covering the villi, in his case, as of both the type of Langhans' and syncytial cells. The mention of a "heaping up" of the covering epithelium (Waldeyer) might be regarded as the plasmodial buds seen on normal villi. I am unwilling to assume as positive a stand against Schlagenhauser as that taken by Risel, especially as the case of Pick, immediately to be discussed, must also be considered; but, on the whole, the burden of proof still rests against the assumption that hydatid growth occurs in teratomata.

If we accept Schlagenhauser's view, the theoretical deductions justified in regard to the genesis are not far-reaching. To assume that the presence of degenerated fetal membranes would point to a derivation from an impregnated pole cell instead of from a blastomere is not warranted, as was pointed out by Pick, Steiner, etc. If subsequent observations confirm the findings of true hydatidlike growths it will merely afford another proof of the specific nature of the ectodermal growth, which shows so many characteristics, both physiologic and morphologic, of the chorionepithelium of pregnancy.

HYDATID DEGENERATION IN A TERATOMA OF THE FEMALE.

The most interesting and also most convincing case bearing on this subject and corresponding to a non-malignant hydatid in a teratoma, is the one described by Pick,¹⁷ but in this instance also a reasonable amount of doubt remains, and further confirmation will be required to set the question at rest.

On opening the abdomen of a woman of 30, who was operated on for ectopic gestation, in addition to the tube, which contained a few chorionic villi, a dermoid was discovered. The dermoid was typical of its kind; but within a subsidiary cyst of some size and completely separated from the rest of the growth as well as from the ectopic sac, were numerous hydatid bodies, which in both their gross and microscopic morphology corresponded to intrauterine hydatidiform degeneration of the chorion.

In discussing this case, Pick believes that the origin of the hydatid from the tubal pregnancy can be absolutely excluded. The growth is separated everywhere by a fibrous cyst wall; the formation is old; the tubal pregnancy recent. He regards it as a part of the original dermoid "anlage," a closed portion of the membrana chorii, the cyst as a portion of the intravillous space filled with serous fluid instead of blood. This case, in Pick's opinion, confirms Schlagenhauser's thesis, except that the question of a pole cell vs. blastomeric origin can not be decided by this or similar observations. What it does show is that Marchand's view, that a congenital anlage arises at the earliest formative stage, is correct.

With Risel, I hold that this case is open to some doubt. If the early tubal pregnancy had not produced the hydatid formations, this by no means excludes an origin from a previous pregnancy, or unnoticed abortion, by a blood channel later obliterated. It may be objected that a limitation of such metastases to one spot, and, at that, to such an inaccessible one as the center of a dermoid cyst, is inconceivable. I will acknowledge that it is unlikely, impossible it is not. Further evidence is necessary finally to settle this question.

4. CHORIONEPITHELIOMATOUS PROLIFERATION IN TERATOMATA ELSEWHERE THAN IN THE GENERATIVE GLANDS.

The chorioneplitheliomatous proliferations so far dealt with have all, with the exception of Boestrom's case and perhaps my third case, had their origin from the generative glands. Boestrom has not, as far as I know, conclusively shown that the testes were normal, and, as no teratoma of the brain was found, the case is therefore incomplete and can not be classified with any certainty. Bearing the genesis of these tumors in mind, we might expect to find a chorioneplithelioma wherever teratomata occur, as first suggested by Schlagenhauer, and a few observations on record fulfill this expectation.

The case mentioned by Albrecht,⁸⁸ in which the epithelium lining the branching ducts in a teratoma of the liver closely resembled chorioneplithelium, is reported with too little detail to permit the forming of a serious judgment. Judged, however, by what this author says, his assumptions are not justified.

The most convincing and unique case of chorioneplitheliomatous proliferation outside of the generative organs (except that of Djewitzki, which will be next considered and in which no teratoma was found), is Ritchie's.⁷⁹ This case was also examined by Teacher,¹⁰ who vouches for the chorioneplitheliomatous nature of the growth.

In a man 24 years of age, who died of a malignant tumor of the anterior mediastinum, a large neoplastic mass was found jutting from the root of the left lung. The mass was partly cystic and partly solid. The large cyst contained the usual dermoid constituents—hair, sebaceous glands, epidermoid structures, muscle, etc.—and was in direct continuity with the solid part of the growth. The solid portions proved typical chorioneplithelioma. The numerous small nodules scattered throughout the lung were of identical composition.

The description is that of a true chorioneplithelioma from a teratoma. The illustrations of this paper bear out this contention. As good a judge as Teacher agrees with the findings. The teratoid nature of the growth is apparent even if entoderm was not found. This case appears conclusive and incontrovertible evidence in favor of the occurrence of chorioneplithelioma elsewhere than in the generative glands.

Djewitzki⁸⁰ reports a case of chorioneplithelioma of the bladder, which also appears convincing, but has not quite the value of the previous case.

A virgin, 75 years of age (menopause twenty years previous), was cured for hemorrhage, the curettings showing hypertrophic endometritis due to fibromyomata. Death from cardiac failure permitted an autopsy. At this was found metastases in the lungs, bronchial glands, spleen and sigmoid, arising from a small nodular tumor situated immediately beneath the mucous membrane of the bladder. All the tumors were typical chorioneplithelioma; no teratoma was found. The uterus contained only the fibroids previously diagnosed.

Djewitzki scouts the idea of a teratoma with overgrowth of the other constituents by the chorionectoderm. As a possible genesis, he suggests carrying along some of the cloacal ectodermic cells by the Wolffian duct. Another alternative he offers is the reversion to an embryonal type, or *Entdifferenzierung* of the bladder epithelium.

The extreme age of the patient makes any connection with a possible concealed or denied pregnancy unlikely. A latent period of twenty or more years has previously been unknown. That the author has overlooked teratomatous constituents in his examination of the tumor is possible, or that such tissues were obliterated is also

conceivable. I am inclined to regard this case, with the slight reservation already mentioned, as another instance of chorioneplithelioma in the relation of consanguinity (in the sense of L. Pick) to its host. The extremely long latent period of nearly seventy-five years is in strong contrast with the usual course noted in tumors, which are classified as congenital.

5. A DETAILED DISCUSSION OF THE MORPHOLOGY AND OF THE THEORETICAL BASIS OF CHORIONEPITHELIOMATOUS TUMORS.

HISTOGENESIS.

The foregoing has shown that a certain number of tumors of the testicle, also a tumor of the mediastinum, and one of the bladder, which bear a close resemblance to the chorioneplithelioma of the female, are on record. Since Schlagenhauer published his views on the significance of these growths they have been classified as chorioneplitheliomata. Where in direct connection with a teratoma and where the typical characteristics of the growth are well developed, but little difficulty will arise in recognizing their nature. Their recognition will become correspondingly difficult when teratomatous constituents can not be demonstrated (as in my first case), and where, through unknown causes, deviations from the so-called typical type of Marchand appear. In such cases it would be desirable to have one or more distinctive or pathognomonic characteristics in mind to decide the question; and we now must try to determine whether such exist.

As has just been stated, the embryonal nature of the tissue can often be shown by its occurrence in a teratoma. Its ectodermal origin has been conclusively proven in a number of cases—in Pick's ovarian teratoma in a girl of 9 years, in Risel's case, in both of which the syncytium was in direct continuity with neuroepithelium, and in my own Case 2, in which the cells of Langhans type were continuous with the epidermis, and then diffusely invaded the stroma, gradually, but without a break, merging into the papillary and atypical type of chorioneplithelioma. This continuity proves merely that we are dealing with an embryonal ectodermic tissue, but does not show that the cells are specifically chorioneplithelioma. To look for such highly specialized characteristics as the hair found in the epidermis, or the nerve cells found among the brain substance of embryos, would be futile, for the chorioneplithelium is a primitive tissue, and normally never reaches a higher stage of development.

SYNCYTIUM, ITS VALUE AS A DISTINGUISHING MARK.

At one time it was supposed that the syncytium would prove a sufficiently specific structure to assure the diagnosis, but subsequent observations have inclined some authors to doubt this. In the first place, the term syncytium has been very loosely employed. According to Bonnet,⁸¹ multinuclear protoplasmic masses should be divided into plasmodia, masses which have not yet undergone subdivision; syncytia, composed of a fusion of pre-existing separate cells; and symplasma, or cells which are undergoing a degenerative process during which, at a certain stage, a real or apparent fusion exists. In pathologic material we are unable to decide whether we are dealing with the first or the second, and as far as chorioneplithelioma is concerned, this is of no significance if we accept Marchand's view that syncytium and Langhans' cells are merely an expression of various functional activities of the villous covering; we even do not know which is the first to appear in the human

embryo. Symplasma should be recognized by the degenerative changes, most readily appreciated in the nuclei, where they take the form of fragmentation, pyknosis, etc.

The most typical syncytium has a deeply staining homogeneous protoplasm, with well-preserved and numerous nuclei, vacuoles often containing red blood cells, and, under favorable conditions, a ciliated margin (Pick, Wlassow, etc.). Syncytial formations have been found in various inflammatory conditions, such as pneumonia and nephritis (Aschoff⁸²), in carcinomata and endothelioma (Recklinghausen⁸³), in adenocarcinomata gigantocellulare of the liver (Babes⁸³), in the uterine mucosa in ectopic gestation (Schmidt⁸⁴), etc., which seems to rob them of much of their specific or diagnostic value. Another possible source of error has been pointed out by Sternberg,⁸⁵ who showed that material preserved in formal-Müller lost some of the sharp cell outline, and consequently could simulate syncytium; but this artifact would still be unable to account for typical arrangement, etc. A careful study of thin sections stained by various methods will often show a tissue to be composed of discrete cells, which in thick sections or to cursory examination will appear fused and syncytial. Whether the syncytia or giant cells described by these various authors really ever so exactly correspond to or simulate the syncytium of true chorionepithelioma, with its cytologically distinctive marks (vacuolization, ciliary margin, etc.), I hesitate to affirm.

I have a tumor of the arm from a man of 77, which is a polymorphous-celled carcinoma composed of large, often polynuclear cells, which resemble syncytium, but yet do not answer to all the characteristics which should be considered necessary. Such a tumor should not be classed as a chorionepithelioma, but, on the other hand, should also not be used as a possible proof against the specific nature of syncytial formations.

DOUBTFUL TUMORS.

The tumor of the liver described by Marx⁸⁶ gives the impression of being a chorionepithelioma; whether primary or secondary must be left undecided; that of Michel certainly must be considered of chorionepitheliomatous nature (or chorionectodermal, to employ the nomenclature of Pick, who subjects it to a convincing critique⁸⁷). Neither of these articles offers any evidence against the doctrine of chorionepitheliom in teratomata.

Sternberg⁸⁸ recently reported a tumor of the testicle in a man of 26, which caused metastases in the liver, lungs and retroperitoneal glands. Both tumor and metastases were composed of light cubical cells about the capillary blood vessels, and of syncytial masses in close connection with the vascular endothelium. He classifies this tumor as a sarcoma in the sense of Malassez and Monod with vasoformative function, without supplying any new facts, except that he claims to have found syncytium arising from the maternal endothelium in young human embryos. Sternberg concludes that many, if not all, so-called chorionepitheliomata in teratomata are sarcoma or endothelioma. In the discussion which followed no additional facts were brought out. It will be of interest to see whether the promised fuller report will prove more convincing.⁸⁹

CHARACTERISTICS OF THE NORMAL TROPHOBLAST.

But for the sake of excluding all sources of error, let us set aside syncytium as a pathognomonic structure. We then fall back on certain general or group characteristics to distinguish the chorionepitheliom. It is true that the further the tumor tissue departs from its normal prototype the more difficult and questionable will its comparison become. It is by a careful study of the normal chorion of the villi and of the chorionepitheliomata

of the female, in direct connection with pregnancy, that we can alone hope to recognize the similar tumors, independent of gestation, arising from a teratomatous growth.

The normal trophoblast shows three varieties of cell forms—the Langhans type or zellschicht, the so-called chorionic wandering cells, and large plasmodial or syncytial bodies. Even in the chorion of pregnancy these constituents vary in their numerical relations and arrangements, not only during different stages of pregnancy, but also in individual cases. These variations become more marked as we turn to the pathologic formations, such as hydatids and chorionepitheliomata. The normal trophoblast shows certain physiologic properties (morphologically recognizable), which distinguish it from other normal tissue (unless we except the single instance of the erosive action of the osteoclast during normal bone processes), in that it invades the structures of the uterus and erodes them. This invasion, though physiologic, corresponds exactly to the invasion of malignant tumors, although usually, unlike these growths, it reaches a definite end. But in the malignant neoplasms of pregnancy—hydatid and chorionepithelioma—the process goes further, boundless and destructive proliferation results, with ultimate harm to the whole organism. This erosive action of the normal chorionectoderm follows along certain well-defined lines. The cell columns invade the decidua and also muscular tissues after the type of a carcinoma, or more diffusely so as to simulate sarcoma, sending the active chorionic wandering cells far into the structures of the host. These cells appear attracted by the blood vessels, erode their coats, creep along beneath the vascular endothelium, finally entering the lumen and causing perivascular hemorrhages. As the rapid increase in number of cells is not accompanied by a corresponding, in fact, by any, formation of new vessels, the tissues would at once be subject to lack of nutrition and consequent necrosis, were not some osmotic or other transfer of nutritional substances possible. This osmotic function would seem to be attended to by the large syncytial sheets or surfaces which, according to Bonnet, not only where in direct contact with blood, but also when more distantly removed, show a hemoglobin contents, in distinction to the other trophoblastic cells, which show such blood pigment only at their edges, where postmortem diffusion might account for it. Hofbauer⁹⁰ has actually shown the loosely combined iron in the basal layer of the syncytium, and has followed it into the stroma of the villus.

In the pathologic forms already referred to, necroses form a large part of the tumors, as the vascular supply, especially in the metastases, is often insufficient; wherever, however, the blood supply is abundant and readily reached, as in the liver and lungs, the metastases show well-developed and prominent syncytial forms. In addition to the characteristics so far brought forward, the chorionectoderm appears to exercise a destructive (lytic, if I may call it so) action on neighboring cells independent of pressure necrosis, and accompanied by the extensive formation of fibrin, which last may very possibly be traced to the hemorrhages.

To recapitulate, the normal trophoblast is composed of three cell forms, which proliferate rapidly, invade the blood vessels, cause hemorrhages, necrosis and fibrin formation, and having fulfilled their function during gestation show no further malignant properties. These same cells appear in the malignant growths of pregnancy, evince the same properties, but fail to stop be-

fore causing harm to the host. Once having entered the blood vessels, rapid and fatal metastases occur, metastases often faithfully copying the primary growth. Such tumors, whether they assume the typical or atypical form of Marchand, are recognized and accepted when in direct connection with pregnancy, partly because of this relationship, partly because they so faithfully copy the normal trophoblast. Were we to analyze each cell, nothing more characteristic would be arrived at than the analysis of a single cell taken, let us say, from a carcinoma or from a sarcoma. Again, no one property here mentioned is strictly limited to this form of growth. Sarcomata are often hemorrhagic, carcinomata metastasize through the blood vessels (Goldmann,²¹ etc.).

Such properties as the glycogen contents of the Langhans cells are shared by many varieties of growths, although Lubarsch²² is inclined to consider it a sign, though not a sure one, of the embryonal derivation of a tumor. Attempts to use the size, by actual measurement, of a cell or its nucleus, as a means of comparison or identification, are, of course, of uncertain value.

"TYPICAL" AND "ATYPICAL" FORMS OF MARCHAND.

The description given by Marchand of the two main types of tumor found in connection with pregnancy is so excellent and applies so well to chorionepithelioma in teratoma, that I will quote it in full.

"Those cases are typical in which the characteristics of the chorionepithelium which appear in the first period of gestation are represented, with no or but slight variation. They show well developed, continuous syncytial masses of the form of irregular, multinuclear strands and branching protoplasmic processes, and with more or less well developed and numerous transparent polyhedral cells of the structure of the zellschicht. Whether the Langhans cells can be wholly absent, as has been described in some cases, I am by no means certain. If they are not found in some spots, that is no proof that they are completely wanting."

"Those cases are atypical in which everywhere, or at least almost everywhere, the chorionepithelium has lost its peculiar normal grouping, and occurs only as isolated cells, which may show various forms. The cell masses which form the surface and inner layers of the decidua serotina (basalis) in hydatid mole may be taken as an example or pattern of these forms. The cells rarely show the habitus of the delicate, transparent membranous and sharply circumscribed zellschicht elements, with regular, oval nuclei, frequent mitoses and glycogenic cell protoplasm. More often their habitus is that of compact, more deeply staining and very irregularly shaped cells, with nuclei varying greatly in size, sometimes attaining enormous proportions and showing intense and often equal staining properties, which allow the recognition of their syncytial character. These elements may form multinuclear aggregates, but in many cases no large syncytial masses develop. Transitions between the two chief varieties may occur if, here and there, larger syncytia are formed."

VARIATIONS FROM MARCHAND'S TYPES ENCOUNTERED IN TERATOMATA.

Further on in the same article, but without emphasizing this point as markedly, Marchand says: "Tumors of the chorionepithelium may show certain resemblance with ordinary carcinomatous tumors." In the testicle particularly, this large alveolar type may predominate, the chorionepitheliomatous type cropping out at some small spot or first becoming manifest in the metastases. The testicle tumors described by Ribbert²³ (p. 619) impressed Pick as probably chorionepithelioma, and their further study might show typical formations. The growth described by Askanazy²⁴ and my own Case 2 vary still further from the accepted types of chorionepithelioma, as the Langhans cells line cystic and papilliferous configurations hardly even suggestive of the group under

discussion, but betraying their true nature by entirely typical spots which are in direct continuity with the papillary formations. Lately, Pick²⁵ has reported a case of carcinoma of the liver in a female, which he claims is a true chorionepithelioma because of its morphologic characteristics. His explanation is based on the theory that this apparently simple tumor is a teratoma with its other tissues undeveloped. Although far from denying the possible truth of his conclusions, the proof offered in this or in similar observations, if more should be forthcoming, is very weak unless we accept the group characteristics previously discussed as sufficiently convincing, even when unaccompanied by a demonstrable teratomatous origin. It is also tempting to generalize and use such a case as an argument for the embryonal derivation of all tumors (or the converse, as an emphatic proof against their parasitic origin, as Pick has done).

IS CHORIONEPITHELIOMA A "SPECIFIC" TUMOR?

There is another possible aspect of the discussion to which I turn with great hesitation, as it involves not only the debatable question of metaplasia, but also the "specificity" of chorionepitheliomatous tissue. We have seen that syncytium and Langhans cells, or at least structures morphologically their equivalent, in direct continuity with unequivocally ectodermal tissues, have been noted by Pick, Risel and myself. Pick and Risel both regard this fact as a proof that the anlage from distinct fetal membranes, such as Schlagenhauser has assumed, is not a requisite. Why not generalize still further, as Lubarsch²⁴ has done, and consider it merely as an evidence of a metaplastic change of any embryonal ectodermic structure, which under certain unrecognized conditions is capable of producing this variety of tumor tissue, just as in response to other stimuli it undergoes carcinomatous changes or degeneration (Taufier,²⁴ Yamagawa²⁵). By this view we would regard the chorionepithelioma as a secondary malignant degeneration of a teratoma, or, where no teratoma is found, a degeneration of the tumor "*Keim*," which gives rise to chorionepithelioma or carcinoma, depending on the nature of the stimulus. Against this view only one valid argument can be advanced, but it is of almost overwhelming force, and that is the coincident metastasizing of other teratomatous constituents. To explain the composite metastases various hypotheses have been offered (see above), the most plausible being the carrying into the circulation of tumor cells which are closely related to, or the equivalent of, blastomeres, and therefore able to differentiate into all three embryonic layers. As in the resulting composite metastasis, the chorionepithelium is again the only actively "malignant tissue," we must assume that the stimulus causing this excessive proliferation is general and evenly distributed within the organism so as to act on the newly formed metastasis at this new site, which is unlikely; or that the blastomeric metastasizing cell contains among its other potentialities that of forming chorionepithelium, which therefore again attains the dignity of a specific tissue.

It would seem, therefore, that this way of regarding the question, and it is not as an advocate of either metaplasia or anaplasia that it has been suggested by me, but merely as a possible train of reasoning, offers no further light on the subject and, in fact, leads us back directly to the other hypothesis. It does, therefore, strengthen, in a negative way, the conception of chorionepithelium as a specific type of tissue, as an integral part of the teratoma, and not merely as an accidental conglomeration of cells, which bear a superficial resem-

blance to the trophoblast through some vagary of growth. Of still greater and, in fact, of decisive value would be a convincing case of hydatid proliferation in a chorion-epithelioma; for if the chorioneplitheliomatous tissue is shown to undergo the same degeneration as the tissues of the true chorion in pregnancy, no one could deny its exact and specific equivalency. As yet the case of Breuss-Schlagenhauser is the only one which approaches this requirement, and as long as these hydatid-like forms are still under suspicion of being a merely accidental imitation due to physical forces, it can not be used in evidence.

6. CLINICAL ASPECT AND SYMPTOMS OF CHORION-EPITHELIOMA OF THE TESTICLE.

Of the 22 above-cited cases, including my own, the 4 cases of Wlassow are without any clinical data. Schlagenhauser's has but very scanty observations; Schmorl's Case 2 at the time it was reported was too recent to be of service, likewise my own Case 2. In Steinhaus' case and my Case 1, the subsequent course could not be ascertained; consequently, only 13 cases can be utilized in trying to present the course of this variety of tumor. Boestrom's case and my Case 3, respectively, presented the symptoms of a tumor of the brain and tumor of the mediastinum, without a primary neoplasm of the testis being convincingly excluded.

The youngest patient was 16 years of age, the oldest 43; but the great majority were found in young adults in the early twenties. As the local testicle symptoms were absent or at most consisted of enlargement of one testis with very slight pain, the patients more often presented themselves on account of abdominal symptoms due to the metastases, and when all hope of a radical cure had passed.

The average duration of the disease can not be accurately determined, for the patients were unable to state when the testicular enlargement had begun, or in some cases this enlargement was never sufficient to attract attention. The longest duration was that of my Case 1, in which the testicle had been appreciably increased in size for two years. Probably the usual course will be found to be less than twelve months. Trauma was repeatedly followed by a sudden increase in size and the appearance of the metastases.

The symptoms varied greatly, but, except for such local discomfort due to the testicle tumor, which in a few cases reached the dimensions of a child's head, were confined chiefly to the abdomen and lungs. The retroperitoneal glands along the iliac fossa, and those situated higher up along the aorta, caused intestinal and stomach pressure symptoms. In one case only was jaundice noted; in several others the liver palpated, greatly enlarged and nodular. A transient edema of the leg followed operation in the case described by Carnot and Marie. Cough, dyspnea, blood-streaked or bloody expectoration were almost constant terminal symptoms, readily accounted for by the frequency of the lung metastases. The high fever in my Case 3 was probably due to necrotic mediastinal and lung tumor masses; in Scott and Longcope's patient the symptoms on admission were those of a tubercular pleurisy. The involvement of the kidneys was never manifested clinically. Rissel's Case 2 had a transverse lesion of the cord due to the pressure of the metastatic tumor tissue. Toward the end, loss of weight and general cachexia were prominent symptoms in all.

Clinically, chorioneplitheliomata of the testicle, therefore, show no very distinctive course. Like other malig-

nant tumors of these organs, they are rapidly fatal; metastases, both in near and in distant organs, occur early and usually are too far advanced when first seen by the surgeon to permit of a radical cure.

7. SUMMARY OF OBSERVATIONS AND DEDUCTIONS BASED ON THEM.

1. In the female, direct continuity of malignant and non-malignant hydatids and of true chorioneplitheliomata with the epithelial covering of the fetal villus has been repeatedly observed, thus proving these tumors to be composed of fetal ectoderm.

2. A similar continuity of tissues has been noted in the covering of deported villi, which acted as the starting point of metastases, arising from hydatids or chorioneplitheliomata. This affords additional proof that the metastases are likewise derived from the fetal ectoderm.

3. Theoretical considerations point to the similarity of the embryologic processes which produce the normal fetus and the embryoma or teratoma. The theory of Marchand and Bonnet traces the origin of these growths from impregnated pole cells or early blastomeres, which are liberated from the cell complex, remain latent for a longer or shorter period, and then, in response to as yet unknown stimuli, resume their growth with the still inherent property of forming all the structures found in the normal embryo.

4. The resulting tumors, genetically the twin of their host, may be highly complex, imitating the normal embryo in a startling fashion; or very simple, so that they afford but little clue to their teratomatous origin (single tooth, thyroid tissue, etc.). Transitions between the complex (embryoms, teratomata, dermoids) and simpler forms (biderms, mixed tumors, etc.) can be traced (Bonnet). Such teratomatous growths have been found in the ovary, testis, retroperitoneal space, mediastinum, brain, sacral region, etc.

5. Among the tissues found in these tumors, ectodermal structures often take a leading part. Neuroepithelium, skin and chorioneplithelium have been found in direct continuity surrounded by the most diverse tissues. Wherever teratomata occur chorioneplithelium may be looked for (though, of course, it does not occur in the majority of cases).

6. Consequently, these ectodermal structures are of equal significance, and it becomes unnecessary to assume a separate anlage of fetal membranes to account for the presence of chorionectoderm.

7. To the chorionectoderm, in teratomata, one must also accord a distinct and specific significance, like that accorded to a special tissue such as skin or brain substance, because in most of the recorded cases it shows all of the characteristics of the trophoblast of pregnancy. These characteristics are not only morphologic (the three types of cell forms—Langhans cells, syncytium, chorionic wandering cells—absence of vessels, etc.), but also physiologic (vaso-destruction, fibrin formation, glyco-gen production).

8. As in the chorioneplitheliomatous tumors in direct connection with pregnancy, the chorionectoderm in teratoid tumors also assumes atypical forms, which render its recognition difficult, and perhaps, in some cases, impossible.

9. These atypical forms may present a tissue similar to the so-called atypical form of Marchand, or, as the result of an excessive growth of Langhans cells, a more diffuse alveolar carcinomatous, papillary, cystic, or perithelial arrangement may be found.

10. The true nature of these atypical forms of tumors

can be recognized by discovering teratomatous constituents and typically chorionepitheliomatous portions, in direct continuity with, or in gradual but unbroken transitions to, the less characteristic parts.

The foregoing chain of evidence is not weakened by the arguments advanced by certain authors. Granted that syncytium is not confined to chorionepithelium alone (although typically foamy syncytium with vaso-destructive tendency and eiliary margin has not been found elsewhere), the recognition of chorionepithelium is not based on any single morphologic fact! True to its prototype in normal gestation, the chorionepithelium evinces a high proliferative activity, shown not only in the primary tumor, in the simple metastases, but appearing also in the composite teratomatous metastases, in which it again forms the "malignant" element.

To expect the chorionepithelium to differentiate into higher tissues, like the other tissues dating from "the earliest anlage" of the teratoma, is as reasonable as to look for a similar differentiation of the placental tissues, which are also examples of cells derived from "the earliest anlage," and which nevertheless retain their early embryonal characteristics throughout the long period of gestation.

In order to interpret the close connection of the chorionepithelial tissues as a "vasoformative" function and to derive their genesis from the endothelium of the blood vessels (as was done by Malassez and now again by Sternberg), it is necessary to ignore their direct continuity with certain undoubtedly ectodermic structures, such as epidermis or neuroepithelium.

I wish to thank Prof. T. M. Prudden for placing the resources of his laboratory at my disposal, and also for much interest and advice during the progress of this study. I am greatly indebted to Prof. F. C. Wood for the material of my two testicle cases, and for much aid and many helpful suggestions. Dr. Ludwig Piek (of Berlin) has very kindly given me valuable advice and criticism through several private communications, for which I take this occasion to thank him.

6 East Eighty-first Street.

CHRONIC ACETANILID POISONING

WITH REPORT OF A CASE DUE TO ABSORPTION OF THE
DRUG FROM AN ULCER OF THE LEG.*

JAMES B. HERRICK, M.D.

AND

E. E. IRONS, M.D.
CHICAGO.

It is well known that an overdose of acetanilid may produce alarming or even fatal results and that with an average dose the same untoward symptoms may follow in one who, because of idiosyncrasy, is peculiarly sensitive to the influence of the drug. There are few physicians who have used the remedy at all extensively who have not at times seen more or less pronounced cyanosis, feeble pulse, subnormal temperature, sweating, yawning, nausea, vertigo, perhaps syncope or marked symptoms of collapse, follow its administration.

The literature abounds in reports of acute toxic symptoms after acetanilid. Some of these doses have been small, 1.5 to 5 grains, yet, on the other hand, large doses have been borne with impunity. I have known 30 grains at a dose to be given for the relief of pain, this amount being often repeated, yet no unpleasant results followed. Hargreaves¹ reports 30 grains (450 grains) as having been taken without a fatal result. Elmquist² saw a woman who had taken 8 grams (120 grains) with suicidal intent. Though the stomach was not washed out until two hours after the ingestion of the drug, recovery followed, and there were, in fact, at no time any very alarming symptoms.

While these acute dangers attending the use of acetanilid are recognized by the profession, and even to a limited extent by the intelligent layman, it is not so well known that the long-continued use of acetanilid is attended by fairly definite poisonous effects and that idiosyncrasies exist analogous to those seen in acute poisonings, accounting for the fact that some individuals are unable to tolerate an oft-repeated dose of the drug that is easily borne by another. Chronic poisoning may escape detection because the symptoms in some instances are not pronounced; their onset, too, is often very gradual, even insidious; they mimic the manifestations of other diseases or are partly obscured by symptoms of the primary disease for which the drug was taken, so that it is often no easy matter for the physician to recognize the existence of toxic effects. And especially is it difficult when he is unaware of the fact that the patient is taking the drug or when, as so often happens, the patient persistently denies the existence of any drug habit.

It is fitting, therefore, to call attention to the clinical features attending the chronic use of this drug, so that they may be better known, and it seems an opportune time to review the subject of chronic acetanilid poisoning, for several cases have recently been reported, and the committee on chemistry of the Council on Pharmacy and Chemistry of the American Medical Association has just told us of the large number of patent and proprietary remedies containing this drug. The spread of such knowledge as that contained in this admirable report, as well as the knowledge as to the symptoms and dangers of chronic poisoning, ought to make physicians and laymen more cautious in the handling of the remedy

and help kill its wholesale and indiscriminate use in the many nostrums now on the market.

In the present paper we shall first report a case of chronic poisoning by acetanilid, the drug being absorbed from an ulcer of the leg, in this respect the case being unique. The results of a study of the blood and urine will then be detailed, as well as some animal experiments. Lastly, the attempt will be made to draw from the study of this and other reported cases a clinical picture of this condition and to show how a study of acetanilid poisoning may possibly throw light on other forms of disease attended by somewhat similar changes in the blood, urine and spleen.

REPORT OF THE CASE.

Epitome of the Case.—A woman, aged 50 years, for seven years applies acetanilid to a large chronic varicose ulcer of the leg. She has had more or less general nervousness, mental depression, weakness, dyspnea, cyanosis, palpitation, and is found cyanotic. Stopping the use of the drug causes maniacal excitement and gives proof of her being addicted to its use. The liver and especially the spleen are enlarged. The blood shows a moderate degree of secondary anemia. There is no hemoglobinemia or methemoglobinemia. Urine, dark in color, shows paraamidophenol and increase in ethereal sulphates. There is no albumin, sugar or casts, and no methemoglobin. Animals after being given acetanilid for a long time show only slight blood changes; splenic changes also slight, though in one dog an appreciable increase in the amount of connective tissue. Patient recovers after gradual withdrawal of the drug.

History.—Mrs. A. W., American, aged 50 years, widow, cook by occupation. Family history negative. Patient did not have any of the diseases of childhood. There is no history of venereal or other infectious disease. Menstruation was regular until two years ago, when the flow ceased. Patient was married at 23; never pregnant. With the exception of trouble with the left leg, the patient was in good health up to five years ago.

Present Illness.—From early girlhood the veins of the legs were prominent, particularly on standing. At 20 years of age one of the veins of the left leg ruptured, bled profusely, and later the leg became ulcerated and this ulcer has never completely healed. Ten years ago the ulcer was skin-grafted, with no permanent benefit. For the past eight years the ulcer has involved the entire circumference of the leg and has remained unchanged in size and symptoms. For the past seven years the patient has applied daily a powder to the ulcer for the relief of pain. This powder was obtained from a veterinary at a cost of \$2 per pound, a pound lasting about one month. Four years ago there was some pain in the right heel and ankle of a rheumatic character, but no swelling or redness of this or any other joint.

For five years the patient has had attacks at intervals of about six months, characterized by weakness, shortness of breath, hot flashes, with sensations of fever over the body, sweating and mental depression. After a few weeks of rest the symptoms have disappeared and she has felt as well as usual. Fifteen months ago one of these attacks came on, from which the patient has not recovered as before. Rest in the country improved the general condition somewhat, but recently the weakness, shortness of breath and pallor have increased.

On admission to the hospital she complains of weakness, hot flashes over the face and body, sweating, dyspnea on exertion, mental depression, pain and discomfort from the ulcer of the left leg. The appetite is good, bowels are regular. There are no headaches or vertigo.

General Examination.—The patient is a rather large, middle-aged woman, of medium height, weight about 170 pounds. General appearance anemic. The face and hands are of a dusky, slightly icteric tint. Lips and finger-nails are bluish. Musculature is flabby. Mental condition good.

The pupils react rather sluggishly to light, but normally to

* Read by invitation, at the meeting of the County Medical Society, Philadelphia, Jan. 10, 1905. The report of this meeting, with the discussion, appears on page 379 of this issue.

1. Hargreaves: *Petersburg. Wochenschr.*, 1890, No. 8.

2. Elmquist: *Hospitalstidende*, 1904.

accommodation. The sclerae have a slightly icteric tint. The teeth are all but one absent, tongue slightly coated.

The chest is well formed and expands normally on inspiration. The breasts are large and pendulous. The heart is enlarged, the left border of dullness lying 4 cm. to the left of the left mamillary line, the right border at the right sternal margin. A systolic blowing murmur is heard at the apex, transmitted to the left and upward over the precordium. Sounds at the base are impure, but there are no definite murmurs. Pulse 100, rather weak. Temperature 98.6. Lungs negative.

The abdomen is prominent, the walls thick and flabby. There is a small partially-reducible umbilical hernia, and also a reducible right inguinal hernia. The liver is palpable 4 cm. below the right costal arch and slightly tender; its upper border of dullness is at the fifth interspace in the mamillary line. The spleen is palpable, as a rather firm, elongated and flattened mass. It is easily movable and is apparently about three or four times its normal size. The pelvic organs are normal. The entire circumference of the middle two-thirds of the left leg is occupied by an ulcer involving the whole thickness of the skin. The floor of the ulcer is irregular, covered with grayish necrotic material having a foul odor. The edges are sharply defined and thickened. The skin distal to the ulcer is indurated and edematous. There is slight hemorrhage from the ulcerated surface on removing the dressings. A small piece of tissue excised from the margin of the ulcer showed microscopically the histologic changes characteristic of chronic inflammation. The veins of the right leg as well as of the left show a number of varicosities.

The axillary, inguinal, cervical and epitrochlear glands are not enlarged.

Blood Examination.—Red corpuscles, 3,528,000; white corpuscles, 12,000; hemoglobin, 40 per cent.; color index, 0.57. In the fresh specimen the red cells were about normal in size and shape, although there were a few rather small cells present. Smears stained with Ehrlich's triacid stain showed a slight poikilocytosis, but no nucleated red cells. A differential count of 250 leucocytes gave 9.6 per cent. small mononuclear, 4.8 per cent. large mononuclear, indented nucleus and unclassifiable; 84.6 per cent. polynuclear neutrophils.

Urinary Findings.—On admission the urine was clear, dark amber in color, acid, specific gravity 1022, no albumin, no sugar; no blood-pigments nor bile-pigments were found, although with nitric acid a dark color ring appeared, resembling that found in urine after the administration of coal-tar products. There were no casts nor red cells, but a few leucocytes were present.

Ophthalmoscopic Examination.—Some time after admission an examination of the eyes showed no retinal changes.

Diagnosis.—The dyspnea and cyanosis seemed out of proportion to the cardiac and pulmonary findings and the powder used for so long on the ulcer was examined as a possible cause. The powder, of the nature of which the patient was ignorant, was tested as to solubility, chemical reactions and melting point, and found to correspond in all respects to acetanilid. Further tests revealed no admixture of other common drugs or alkaloids.

A few days after admission the application of the acetanilid to the ulcer was stopped. This was followed within twelve hours by symptoms of extreme nervousness and excitement bordering on the maniacal, and the patient complained bitterly of pain in the affected leg, so that it was found necessary to restore the drug for the time and to restrict the amount gradually. Acetanilid from the drug room was applied on several occasions in place of the powder brought in by the patient, with the same effects. Coincident with the withdrawal of the acetanilid a gradual improvement in the condition of the blood was observed.

Further Blood Examinations.—Soon after admission, before any reduction in the amount of acetanilid, examination showed red corpuscles 3,864,000 and 60 per cent. hemoglobin. The blood was dark, but at no time showed any marked brown or chocolate tinge. Five examinations for methemoglobin were made with negative results. There was no hemoglobinemia.

The coagulability was slightly decreased. There was a moderate poikilocytosis observable in the fresh specimen. In the stained specimen there were a number of microcytes, an occasional macrocyte; and one nucleated form (normoblast) was found in counting 250 whites. Polychromatophilia was moderate. The leucocyte count was 9,900. A differential count of 250 gave 13.6 per cent. small mononuclear, 5.6 per cent. large mononuclear, 0.8 per cent. mononuclear neutrophils and 78.8 per cent. polynuclear neutrophils.

Two weeks after the entire withdrawal of acetanilid the blood count was 5,500,000 reds, 5,100 whites, 69 per cent. hemoglobin, coagulability normal, no poikilocytosis, though the red cells averaged somewhat smaller than normal.

The patient has remained in apparently good health, has gained about fifty pounds in weight, color is normal, heart action normal aside from the persistence of a slight systolic murmur, spleen and liver reduced in size. The last blood count showed the red cells 5,550,000, whites 11,800, hemoglobin 100 per cent. The slow healing of the ulcer with skin grafts; the deformity from cicatrices declared by the surgeon, Dr. J. B. Murphy, to be irremediable, led finally to the advice to have the limb amputated. This was successfully done above the knee and an artificial leg can now be worn.

DETAILS OF URINARY FINDINGS.

As already noted, the urine presented a number of interesting characteristics in color, amount and chemical constituents. Daily twenty-four-hour specimens were examined for a period of three months from the date of admission, during which time the amount of acetanilid applied to the ulcer was gradually decreased and the effect on the urine, blood and general condition of the patient noted. On admission the patient was applying from $\frac{1}{2}$ to 1 ounce of acetanilid crystals to the ulcer daily.

Amount.—The total urine in twenty-four hours varied from 1,300 to 2,800 c.c., average about 1,800 c.c., with an average specific gravity of 1.015.

Color.—The color of the urine when passed was dark reddish amber, at times resembling port wine, becoming gradually darker on standing, until after several days the specimen was brownish black, indistinguishable in color from a concentrated solution of Bismarck brown. Fresh specimens were repeatedly examined for blood, hematin, hematoporphyrin, indican and the bile-pigments with negative results. Fehling's solution (Haines' modification) was not reduced. Cover-glass preparations of bacteria, such as *B. coli communis* and *B. typhosus*, took a light brown stain when immersed in the urine for an hour. Celloidin sections of various tissues showed a diffuse brown staining of the connective tissue when treated for a short time with urine that had been allowed to stand in the light for a few days. An aqueous solution obtained by carefully evaporating the ether extract of the pigment from the urine gave the color reactions of paramidophenol; the alkaline solution became violet on exposure. With bleaching powder there was produced a violet color, changing to green.

The color of the urine became gradually lighter and the quantity smaller as the acetanilid was decreased until, on its entire withdrawal, the urine was light yellow, remaining unchanged in color on standing, with an average total urine in twenty-four hours of 1,300 c.c.

Paramidophenol.—Specimens of the urine were tested for the presence of acetanilid in the form of paramidophenol, as follows: 100 c.c. of urine were evaporated to 80 c.c., boiled with 8 c.c. of concentrated HCl for three minutes and, after cooling, shaken out with ether. The residue obtained by evaporation of the ethereal extract was dissolved in 10 c.c. of water and 3 c.c. of 5 per cent. carbolic acid added. On the addition of calcium hypochlorite solution, a reddish color appeared, which on adding ammonia became blue. This is the indophenol reaction showing the presence of paramidophenol.

Total Sulphates.—The total, ethereal and mineral (free) sulphates was estimated as follows: 100 c.c. of filtered urine were treated with 5 c.c. of concentrated hydrochloric acid and

3. Allen: "Commercial Organic Analysis," vol. III, part I, p. 213.

4. Webster and Koch: "A Laboratory Manual of Physiological chemistry," p. 65.

boiled for fifteen minutes. While boiling, the sulphates were precipitated by the addition of 2 c.c. of saturated barium chlorid solution. The precipitate, after settling from the warm solution, was removed quantitatively to a filter of known ash, washed till no trace of chlorids appeared in the wash water, dried at 100 C., ignited in a platinum crucible till the weight remained constant, and weighed.

Ethereal Sulphates.—(Salkowski's method), 200 c.c. of filtered urine were treated with an equal volume of barium solution (two volumes of saturated barium hydrate solution and one volume of saturated barium chlorid solution) and filtered through a dry filter; 100 c.c. of the filtrate, containing the ethereal sulphates, were treated as above for total sulphates, except that 10 c.c. of hydrochloric acid were added before boiling.

Mineral Sulphates.—(Found by taking the difference between total and ethereal sulphates.) Several direct determinations of free sulphates, and of the ethereal sulphates from the residual filtrate were made as a control to the above, but this latter method was found subject to slightly greater error and was hence discarded. The results are computed in terms SO_4 .

DETAILS OF TREATMENT AND COURSE.

Throughout the period of these observations (November 20 to February 3) the patient was on general ward diet of fairly constant average composition, the appetite was fair, bowels regular. No coal-tar preparations aside from acetanilid were given, and no other medicine except necessary laxatives, and after the withdrawal of the acetanilid occasional small doses of codoin.

† Trace serum albumin

‡ Extract of 20 c.c. gives good test.

On November 24 the patient was receiving 5 vi of acetanilid applied locally to the ulcer in doses of 3 ii three times a day, somewhat less than she was accustomed to use on admis-

sion to the hospital. The urine was clear reddish amber in color, increased above normal in quantity, but contained no albumin nor sugar. Tests for acetanilid (in form of paramidophenol) were positive. The total sulphates in twenty-four hours were found to be 0.792 gm., of which 0.756 gm. were ethereal sulphates and only 0.036 gm. free sulphates. A few days later, December 9, the acetanilid was reduced to 5iii in twenty-four hours applied to ulcer. Paramidophenol present in urine as before. The total sulphates at this time amounted to 0.805 gm., of which 0.777 gm. were ethereal and 0.028 gm. free. In view of the remarkably low values for free sulphates it was thought that the long continued elimination of ethereal sulphates might have created a poverty of sulphates in the body. On December 12, accordingly, for both therapeutic and experimental reasons, sodium sulphate was given by mouth in doses of 3 ii daily, the other conditions of food and acetanilid remaining unchanged. On December 14 the urine was somewhat lighter in color, the quantity and specific gravity about the same as before. The total sulphates were 1.186 gm., of which 0.668 gm. were ethereal and 0.518 gm. free.

By December 23 the acetanilid had been reduced to 3 i applied locally to the ulcer; sodium sulphate 5 ii was given daily by mouth. The urine was light orange in color and still gave a good test for paramidophenol. The general condition of the patient had steadily improved. There was still some cyanosis, but no dyspnea; heart regular, 72 to 80 per minute, temperature normal. A few days later (December 29) the general cyanosis increased, the lips and finger-nails became blue and the patient fainted on attempting to sit up in bed. The pulse was much weaker and increased to from 84 to 100 per minute, temperature subnormal. The urine was dark amber, resembling that passed on admission. After some search there was found at the bedside a package of acetanilid, of which the patient admitted applying about one ounce during the night to relieve pain.

The acetanilid was entirely withdrawn on January 1, the cyanosis disappeared and the patient began to gain steadily in weight.

On January 23 the urine was light yellow, 2,800 c.c. in twenty-four hours, specific gravity 1013, with trace of serum albumin, no sugar. The total sulphates were 2.626 gm., of which 0.218 gm. was ethereal and 2.227 gm. free sulphates, being approximately the relation of ethereal to mineral sulphates in a normal individual. Two more determinations of sulphates (the patient still receiving 3 ii of sodium sulphate by mouth) showed at the first examination total sulphates 1.971 gm., ethereal sulphates 0.138 gm., free sulphates 1.833 gm., and at the second examination total sulphates 1.828 gm., ethereal sulphates 0.148 gm. and free sulphates 1.680 gm., respectively. Examinations of the urine for paramidophenol were negative.

The patient was then given acetanilid gr. v every four hours, making gr. xxx in twenty-four hours, for three days. After twenty-four hours the pulse showed 56 to 60, temperature 96.4 to 96.8, but no other marked symptoms until the third day, when the patient began to complain of epigastric distress, nausea, difficulty in breathing, tingling in the fingers, extreme nervousness. Lips and finger-nails became cyanotic. Pulse variable, 56 to 80 per minute, weak. Temperature subnormal, 96.4. The urine was dark yellow in color and gave a distinct reaction for paramidophenol with 20 c.c. Two determinations of the sulphates showed respectively total sulphates 1.686 gm. and 3.292 gm., ethereal sulphates 0.592 gm. and 0.475 gm., free sulphates 1.094 gm. and 2.817 gm. These numerous tests show conclusively the distinct increase in the elimination of the ethereal sulphates that follows the ingestion of acetanilid.

ANIMAL EXPERIMENTS.

The effect of prolonged dosage with acetanilid was studied experimentally in a number of animals, the particular object being to see whether any effect would be produced on the spleen.

Guinea-Pigs.—To each of two guinea-pigs was given a suspension of one-half grain of acetanilid in olive oil daily for a period of four weeks. The first pig died at the end of four

weeks. Autopsy showed an extreme tuberculous involvement of the lungs. The spleen and other organs were normal in size and appearance. The second pig increased steadily in weight and showed no symptoms whatever. At the end of four weeks the dose was increased to 1 grain per day, and two weeks later increased to 2 grains per day. This dose corresponded to about $1\frac{1}{2}$ grains of acetanilid per kilo. of weight, or 105 grains a day for a man 70 kilo. in weight, and was continued for five weeks more without producing any symptom. The animal almost doubled in weight during the treatment.

A third pig weighing 475 gm. was given gr. i of acetanilid daily for four weeks, then gr. ii for six weeks more. In this animal the weight decreased gradually and at death the pig weighed 275 gm. At autopsy the heart was found dilated, filled with blood. The liver, spleen and kidneys were rather darker than normal, but otherwise showed no changes. The stomach, intestines and lungs were normal.

Rabbits.—Two rabbits were given gr. i per kilo. of body weight daily for six weeks, then gr. ii per kilo., with no symptoms and steady gain in weight until they succumbed to a disease epidemic in the animal house at the end of two and six weeks respectively. Autopsy showed no characteristic changes in the organs.

Dog.—A young adult dog weighing 12 kilos. was given gr. x of acetanilid daily for ten weeks without producing any symptoms. The general condition of the animal was better at the end of this time than that of his companions. The dose was now increased to gr. xx daily by mouth. The first symptoms appeared after three days in sluggishness and loss of appetite. The dog began to lose weight rapidly and became very weak. On the twelfth day there was inability to support the body on the hind legs, due, apparently, to weakness, as there was no real paralysis present. A small purpuric area 2 cm. in diameter was present on one flank. No hemorrhages in the mouth or elsewhere. Examination of fish and stained specimens of the blood showed the red corpuscles rather pale, but otherwise normal in shape, size and staining reactions. No nucleated forms were found. On the thirteenth day the dog had a series of convulsions of short duration and died the following night.

At the autopsy the animal was found greatly emaciated. There were several purpuric areas over the flanks. The heart was dilated with blood, but showed no pathologic changes. The spleen weighed 13 gm., was moderately soft and flabby, capsule smooth but somewhat wrinkled, grayish red in color, and on section was dry and showed some relative increase in connective tissue. The stomach was hyperemic externally and contained a small amount of dark fluid and a few straws. The mucous membrane was hyperemic, but otherwise normal. The lungs, liver, peritoneum, intestines, kidneys and meninges showed no changes.

Microscopic sections of the spleen showed a marked increase in connective tissue with relative decrease in the spleen pulp. The stomach showed slight hyperemia. The other organs showed no microscopic changes.

REMARKS ON THE EXPERIMENTS.

The failure to obtain the picture of a marked secondary anemia in these animal experiments is worthy of note. Stengel had similar results in his animals, and Dr. Warthin of Ann Arbor informs me that in experimental poisoning by acetanilid extreme cyanosis, weakness and death were easily produced, but the degenerate red corpuscles, normoblasts, poikilocytes, etc., of high-grade anemia were not found. The failure to find uniform blood changes in human beings in this form of intoxication, as well as in the lower animals, must for the present remain unexplained except on the vague ground of idiosyncrasy.

GENERAL COMMENTS ON ACETANILID POISONING.

Acetanilid, as its name implies is anilin $C_6H_5NH_2$, in which one of the hydrogens of the amid group is replaced by the acetyl radical.

Its activity is probably due to the formation of simple derivatives of paramidophenol in the tissues. A rapid formation of paramidophenol,

produces destructive blood changes and tendency to collapse, while the antipyretic effects pass off very rapidly.⁵

Paramidophenol has been found in the urine of patients who have taken any considerable amount of acetanilid, whenever it has been sought for, since Fr. Müller⁶ in 1887 called attention to its presence in the urine in a case of poisoning by anilin.

Jaffe and Hilbert⁷ found in the herbivora (rabbits) that the acetyl group was oxidized to paramidophenol and appeared as such in the urine, while in carnivora (dogs) only a part appears as paramidophenol, the rest being changed to a substance of the formula $C_7H_5NO_2$,

The substances into which acetanilid is changed are joined with sulphuric or glycuronic acids (e. g., paramidophenol-ethereal sulphate). The glycuronic acid is believed to account for the levorotatory property of the urine noticed in some cases.

Cahn and Hepp,⁸ who first drew attention to acetanilid as an antipyretic, believed that some acetanilid appeared unchanged in the urine, at least in dogs. Others, e. g., Möerner,⁹ have failed to find unaltered acetanilid in urine. Müller⁶ and others, since his paper was published, have found the ethereal sulphates of the urine increased, while the preformed mineral sulphates are lessened. This is so in our case, as is well shown by the table. It is interesting to note, in our case, too, the increase of mineral sulphates on giving sodium sulphate.

CLINICAL SYMPTOMS OF CHRONIC ACETANILID POISONING.

Manner of Acquisition of the Habit.—The acetanilid habit, which is apt to be accompanied by poisonous symptoms, is fixed on a patient who takes the drug for the relief of pain; the habit is rarely acquired from the giving of a remedy for its antipyretic effects. The analgesic properties of the drug are well known, and it is a common constituent of headache powders,¹⁰ its cheapness making it preferred by the manufacturer of the proprietary or patent medicine to the other coal-tar derivatives. The habit is particularly apt to become a fixed one in the neurotic and hysterical. But strong-minded individuals, sufferers from real, genuine pain, as in chronic inflammations, sciatica, rheumatism, arthritis deformans, tabes, migraine, tuberculosis of bone, ulcer of the stomach, etc., may become dependent on it for the relief of pain and the securing of sleep. Larger or more frequent doses then become necessary and the sudden withdrawal of the drug is followed by exacerbations of pain, sleeplessness and restlessness, such as are seen in the morphin habitué who has his accustomed opiate removed. We tried the sudden withdrawal of

the drug several times in the case of our patient and there developed a condition bordering on mania. There were great restlessness, anxiety, sleeplessness, crying, complaint of pain in the leg, threats of suicide, and finally, as said, a wild and almost maniacal excitement. Codein was a very poor substitute for the acetanilid. Quiet was always restored whenever acetanilid was given by mouth or sprinkled on the ulcer, and whether the patient was aware or not of the fact that she was getting the drug; in other words, there was no imagination about it, the patient was always calm and quiet when under the drug and always excited without it.

So far as I know, this case is the only one in which chronic poisoning has resulted from absorption through the skin. Acute poisoning by absorption from the open skin has been reported, as by Newton.¹¹ The drug has been used locally for its analgesic and germicidal properties, and is a constituent of certain powders sometimes employed by the dermatologists, e. g. the stearate of zinc with acetanilid, in the treatment of painful or itching affections of the skin.

The *susceptibility* to the chronic use of the remedy varies greatly. Some individuals take the drug repeatedly and in goodly doses and are not perceptibly harmed by it. But in most persons slight or marked evidences of toxemia can be seen. Among the commonest manifestations are the following:

Cyanosis.—Cyanosis may be practically the only evidence of the toxic effect of the drug. Jacksch¹² says he has seen several instances of this character where the toxemia has been acute. Cabot's¹³ case was of this nature and was chronic. Cyanosis seems to be the most constant symptom in both acute and chronic acetanilid intoxication. It may be extreme. It varies in intensity from time to time as the amount of drug taken varies. Its real cause is not always clear. Methemoglobinemia may or may not be present. Cyanosis unaccounted for by ordinary explanations, such as cardiac or pulmonary diseases, should lead to the investigation as to the use, perhaps secret, of the coal-tar derivatives.

Anemia and Blood Changes.—The anemia varies in intensity. It is of the secondary type; the hemoglobin is reduced out of proportion to the reduction in the number of red corpuscles. Yet in Cabot's case polycythemia rather than oligocythemia was present. The blood may show marked morphologic changes, the red corpuscles varying in shape and size, often with irregular, fragmented or free nuclei, and many corpuscles showing polychromatophilia. The normoblast is the nucleated form that predominates, though megaloblasts are also seen. The composite picture of Stengel¹⁴ shows the extent to which the degenerative changes may go. Blood plaques are often increased in number. Basophilic stippling of the erythrocyte is sometimes seen. Leucocytosis is the rule—e. g., in our case 12,000, Stengel's 19,000—the increase being in all the varieties of white corpuscles, though in most cases it has been especially in the polymorphonuclear variety. Intercurrent or accompanying inflammatory or suppurative processes may be the cause of the polymorphonuclear increase. Myelocytes are occasionally found. In our case there was a slight decrease in the coagulability. The blood is usually dark and methemoglobinemia has been noted several times, this interfering with the ordinary color tests

for hemoglobin. In other instances no such change is present. Just why there are these differences is not clear. Perhaps in some cases there is no formation of methemoglobin; in others with more of the drug the methemoglobin is formed in the red blood corpuscle; with still more the hemolytic action is more marked and methemoglobin is found in the blood plasma and appears as such in the urine.⁵

Dyspnea, etc.—A physical weakness and shortness of breath, especially on exertion, are complained of by many of these patients. Palpitation, dizziness, spots before the eyes and tinnitus aurium are also met with, as in any other anemia. It is perhaps rather characteristic of chronic acetanilid poisoning that these symptoms as well as the cyanosis are apt to be variable. This is, in large measure, due to the fact that the amount of drug taken may vary from time to time, and the improvement, both subjective and objective, that follows the cutting down of the dose is often quite remarkable. The depressing effect of acetanilid on the nervous system must account in part for these symptoms, for the degree of anemia is often not marked enough entirely to explain them.

Nervous Symptoms.—Mentally the patients are apt to be "nervous." They are neurasthenic, introspective, imaginative. There may be marked mental apathy and hebétude, even bordering on stupor.¹⁵ And they are as deceptive as to the use of acetanilid as is the morphin victim concerning his drug. They seem to have an acquired moral degeneracy. The dependence on the drug can be proven by suddenly stopping it. Complaints of pain, sleeplessness, restlessness, with weeping and the wildest excitement may follow, and the patient begs piteously for the remedy on which he has learned to depend.

Observations are not numerous enough to enable one to make very definite statements as to the condition of the nervous system. Motor disturbances seem not to be described, except that general weakness is often noted. Sensory disturbances beyond the complaint of pain that is so common seem to be rare. Paresthetic sensations are occasionally described. No definite statements concerning the condition of the special senses or the reflexes seem warranted, though feeble patellar reflex is reported.¹⁵

The Heart.—Weak action of the heart is the rule. The pulse is usually soft, compressible, small and often rapid. The irritability of the heart is shown by the alteration in the rate easily brought about by exertion or by nervous excitement. Endocardial murmurs may be due to previously existing cardiac lesions such as sclerosed valves or to the blood condition—so-called hemic murmurs. Myocardial weakness may result in dilatation with the corresponding physical signs and murmurs of relative auriculo-ventricular insufficiencies. As improvement takes place on withdrawing the drug, the heart may return to its former size.¹⁶

The Alimentary Tract.—The alimentary tract is apt to be more or less disturbed; anorexia with occasional nausea and vomiting may occur. The bowels may be irregular. The loss of weight that is commonly seen after the prolonged use of acetanilid may, in a measure, be accounted for by the malnutrition and the digestive disturbances that are present.

The Spleen.—In some of the cases a marked enlargement of the spleen has been noted. In our case the size

16. See Stengel's case, THE JOURNAL, A. M. A., July 22, 1905.

seemed to vary with the amount of acetanilid that was taken. This possible enlargement of the spleen in long-standing cases of acetanilid poisoning should be remembered, as it may be a valuable diagnostic aid rather than a stumbling block in making us think of chronic passive congestion from non-compensated heart, or of the large spleen of hepatic cirrhosis, leukemia, splenic anemia, polycythemia, etc.

The Urine.—In amount the urine appears to vary considerably. In some cases concentrated and of high specific gravity there has been a diminished amount, e. g., in Stengel's second case specific gravity 1038 and 600 c.c. In our case there was an average output of 1,800 c.c. of a specific gravity of 1015, the variations in amount not seeming to depend very closely on the amount of acetanilid taken.

Albumin has been reported in some of the cases, usually, as in our case, as an occasional trace. In some instances larger amounts have been found, e. g., in Luce's case.¹⁷ Casts are found generally corresponding to the amount of albumin. Cardiac weakness with passive congestion may explain the edema occasionally seen, though genuine nephritis, presumably toxic in origin, may also be present and have an influence in producing the edema. In most cases, however, there is not much more than a trace of albumin with a few casts.

Sugar is not present as a result of the acetanilid ingestion. Yet Fehling's solution is sometimes changed to red by the reduction of the copper. This is probably due to the glycuronic acid that is present in considerable amount. Several observers believe that a part of the paramidophenol is combined with glycuronic acid. When doubt as to the presence of sugar exists control tests, such as the phenylhydrazin or the fermentation tests, can be employed.

The color of the urine is so uniformly dark as to make this a most important diagnostic feature of these cases. The color varies from a dark amber to a deep port wine or even brownish-black tint. The color often darkens on standing. And it may be added that putrefactive changes in the urine do not occur quickly. At least in our case this was so, for the urine even after standing for many days was sweet in odor and free from bacteria.

Various abnormal substances have been regarded as explaining the color. Excess of indican is reported. Hemoglobin, hematin, uroerythrin, urobilin and methemoglobin have been found. Paramidophenol is, however, the substance that has been regularly found in all cases, we believe, where it has been sought for, since Fr. Müller first reported its presence. This derivative of acetanilid seems to appear in various combinations. Some state that it occurs as paramidophenol; others as acetylparamidophenol. Most, however, state that paramidophenol is in union with sulphuric acid, or, in part, with glycuronic acid. Paramidophenol is recognized by the so-called indophenol test already described. The urine is boiled for a few minutes with one-quarter of its volume of concentrated hydrochloric acid, and on cooling, a few c.c. of 3 per cent. carbolic acid solution are added, and then hypochlorite of calcium or dilute chromic-acid solution. Amidophenol gives a red color, and on adding an excess of ammonia the color changes to blue.¹⁸ Certain color reactions may also be obtained.⁵ And the urine on standing may be employed as a staining reagent for bacteria or tissues, as was done in our case.

Acetanilid as such appears but rarely in the urine, though after large doses it may possibly be present. Cahn and Hepp⁸ believe it regularly appears.

There is uniformity of opinion as to the increase in the ethereal or conjugate sulphates in these cases. The method of their quantitative estimation has already been described and can be found in any of the text-books on physiologic or clinical chemistry or urinalysis. The normal ratio of mineral sulphates to the conjugate is approximately 10 to 1. In chronic acetanilid poisoning this will be greatly changed, the conjugate sulphates increasing as the mineral diminish so that the ratio may be reversed and be as 1 to 10, or, as in our case, even much less than this. Normally from 2 to 3 gms. of sulphates are eliminated by the average individual, the ethereal sulphates amounting perhaps to 0.25 gm. The great change in cases of chronic acetanilid poisoning may be seen when we notice the figures in our case, e. g., ethereal sulphate 0.77 gm. and mineral only 0.028 gm. That the ratio will, however, depend much on the amount of sulphuric acid ingested is seen from the increase in the mineral sulphates following the giving of the sodium sulphate.

Recapitulation.—To recapitulate the main points in the symptomatology: We find as the almost constant manifestations of chronic acetanilid poisoning (1) cyanosis that may be extreme, (2) more or less dyspnea and general weakness, (3) dark-colored urine that contains paramidophenol and an increased amount of the ethereal sulphates. Generally present but often a most striking and characteristic condition is the anemia of the secondary type with degenerate and nucleated red corpuscles. Methemoglobin may be present in the blood and in the urine. Dizziness, syncopal attacks, tinnitus, palpitation may be pronounced where the anemia is advanced. The spleen is often enlarged. Anorexia, nausea, vomiting and diarrhea may occur. Nervousness and restlessness are aggravated by the removal of the drug to which the patient has become habituated.

DIAGNOSIS.

The diagnosis is easy if once the condition is suspected. It may, however, be mistaken for other conditions, particularly diseases causing cyanosis or anemia or some of the functional nervous disorders. Cardiac weakness, hemic murmurs or those due to relative valvular incompetency, with the dyspnea may lead to a diagnosis of myocardial degeneration, valvular disease or congenital cardiac lesions. This mistake had been made in some of the reported cases. It is only by a careful study of the physical signs of the heart and of the disproportion between the cyanosis and the other evidences of cardiac incompetency that a cardiac origin for the cyanosis can be excluded. In all cases of cyanosis unexplained by cardiac disease, emphysema and the ordinary causes, intoxication by acetanilid or other coal-tar preparations should be sought for.

Confusion with the anemias might result from the blood examination and from the large spleen, though the degree of cyanosis commonly seen should at once attract attention and arouse suspicion of something different from pernicious anemia, chlorosis or leukemia. Methemoglobinemia should also lead one to suspect something different from the usual anemias. Such large numbers of nucleated red corpuscles with such degenerate forms are certainly rare in the ordinary secondary anemias.

Polycythemia with splenomegaly may be simulated. In one other case of chronic acetanilid poisoning that we have seen (orangeine¹⁹ being the preparation used by

17. Luce: *Amer. Medicine*, Sept. 26, 1903.

18. Neubauer and Vogel: *Analyse des Harns*, 10th edition, p. 614

the patient) there was at first a strong suspicion that the case was one of this type as the number of erythrocytes was above the normal and the spleen distinctly enlarged.

There is, we believe, a large number of patients who are suffering from chronic acetanilid intoxication of mild degree. Some of our perplexing anemic, dyspeptic, neurasthenic, "run down" patients might have their troubles explained, in part, if we but knew of the existence of this drug habit. At times the condition for which the drug was originally taken has entirely vanished, so that there is no excuse for the continued use except habit. Searching inquiry should be made in such cases where other adequate explanation for the symptoms is lacking, as to the possible existence of the acetanilid habit, and it should be remembered that the unfortunate who is addicted to the use of acetanilid may be as prone to conceal the fact and to lie about it as the most morally perverted and depraved morphine habitué. An examination of the urine in these cases may enable us to prove the use of the drug.

CONCLUDING REMARKS.

Treatment.—The treatment of this drug habit is comparatively simple. By gradual withdrawal of the acetanilid, temporary substitution of codein for pains or sleeplessness and the use of tonics, recovery will commonly ensue. Attention to the stomach and bowels is important, as on good digestion largely depends the power of blood repair and the return of weight and strength. Much can be done in the way of suggestive treatment by sympathy and encouragement and by having a frank understanding with the patient as to the nature of the ailment, its dangers and the best way of overcoming them. Difficulties in the way of relapse into the old habits will be encountered unless the patient is in a hospital, sanitarium or at home under the careful watching of a trusty nurse. These patients become in a strict sense addicted to the use of the drug, but it has not the firm hold on them that morphin or cocain acquires on its victims. The habit is, therefore, more easily broken off. While one can not tell how much permanent damage has been done in these patients in the way of injury to heart muscle, kidney, nervous system, blood-making organs, etc., it is remarkable how rapidly they improve and approach the limits of perfect health when the use of the drug has been stopped. Even in the most desperate cases, therefore, one may give a fairly hopeful prognosis.

Nature of Splenic Enlargement.—The spleen in our case was decidedly large and fairly firm, so large as to lead, before the blood examination was made, to the question of a possible leukemia. In several other cases the spleen has been reported enlarged. The nature of the enlargement is not quite clear. It may be spodogenous, enlarging because of extra work thrown on it in disposing of waste matter, the result of blood disintegration, or it may be enlarged as the result of the irritation from paramidophenol or other substances circulating in the blood. That the enlargement is not permanent is shown by our case, in which, with the reduction in the dose of the drug, there was a diminution in the size of the spleen. In our animals very little change in the size of the spleen was produced by feeding acetanilid. In one dog there was a moderate enlargement with some increase in the amount of connective tissue.

The enlarged spleen and the cyanosis, as has been said, suggest cyanosis with splenomegaly, the condition described by Osler and others. The similarity is more striking when we consider cases such as Cabot's, or my

own of the woman with the orangeine habit, in which there was polycythemia. And extremely interesting is the group of cases of enterogenous cyanosis reported by v. d. Bergh,¹⁹ where with intestinal disturbance there was marked cyanosis with much indican in the urine and presumably a great increase in the conjugate sulphates, with sulphohemoglobin in the blood, regarded at first by Stokvis as methemoglobin. Interesting fields for investigation are opened up by this group of cases with cyanosis and some light may be thrown on the subject by a more careful study of chronic acetanilid intoxication as it occurs in man or is induced in the lower animals.

Special Article

THE PHARMACOPEIA AND THE PHYSICIAN.

CHAPTER VI.

CATHARTICS.

Cathartics are among the most ancient of all medicinal agents, rhubarb having been in use among the Chinese for more than forty-five centuries; senna and aloes were also used in ancient times.

Liebig supposed that saline cathartics in concentrated solution withdrew water from the blood by osmosis, thus maintaining the feces in a liquid or semi-liquid state. This idea gave place to Schmiedberg's theory, which attributes purgation to the fact that the purgative salts, being slowly absorbed in the small intestine, come into the large intestine, where they prevent absorption of the intestinal contents, thus keeping the feces soft.

Heidenhain concluded that osmotic pressure and physiologic activity of epithelium are concerned in absorption from the intestine, and that the retardation of absorption by salts is due to a lessening of physiologic activity.

Wallace and Cushny studied the action of cathartics on absorption from the intestine, and found that those compounds which give precipitates with calcium salts retard absorption more than others, and that dilute solutions of saline cathartics retard absorption of fluid from the stomach and small intestine, thus rendering the intestinal contents more fluid and more easily moved through the alimentary canal by peristalsis.

When Jaques Loeb studied the effects of certain salts which cause rhythmic contraction of muscle, he noticed that those which produce muscular twitching and an increase in the excitability of nerves are the same which produce catharsis when they are introduced into the intestine. J. B. MacCallum investigated the effects of saline purgatives when injected subcutaneously, intravenously, and when dropped on the peritoneal surface of the intestine. He found that all the saline purgatives are very much more active when injected into the blood, causing peristalsis more promptly and in very much smaller doses than when given by the mouth. This is also true of their injection subcutaneously or of merely dropping the solution on the peritoneal surface of the intestine. He further found that this action is inhibited by a small amount of calcium chlorid or magnesium chlorid solution, when it is injected, or when dropped on the peritoneal surface of the intestine. This inhibition is entirely analogous to that which occurs with calcium chlorid after stimulation of skeletal muscle by sodium citrate and other salts.

MacCallum also found that the saline purgatives cause a greatly increased secretion into the lumen of the intestine; this occurs even when excised loops of intestine are suspended in saline solution, and he considers this intestinal secretion as much the more important factor in maintaining the feces in a semi-fluid state. So far from admitting that the salines cause purgation by being excreted into the intestine after intravenous injection, he claims that they must be absorbed from the intestine into the blood in small amounts, at least,

¹⁹ Hyman v. d. Bergh: *Deut. Arch. f. Klin. Med.* vol. lxxxix, p. 86.

before they can cause increased peristalsis and the stimulation of the intestinal glands to increased secretion, pointing, in support of this theory, to the much more rapid action when such small amounts are injected into the blood stream, than when they are injected into the stomach or intestine. The stimulation of secretion and peristalsis in excised loops shows that it may be independent of the central nervous system, and the ring-like contractions seen after the application of barium chlorid points rather to its action on the muscular fibers than on the nervous mechanism of Auerbach's or Meissner's plexus, but the precise seat of the action has not been determined. As an example of the minuteness of the dose required when the drug is applied to the peritoneal surface of the intestine, it is stated that three-fourths of a milligram (1/80th grain) of barium chlorid caused peristalsis in the rabbit.

Vegetable cathartics, such as cascara sagrada and rhubarb, were also found to be much more effective when used intravenously or subcutaneously than when given by the stomach. Their action is also inhibited by calcium chlorid, but to a less degree than in the case of salines.

While these experiments are interesting in explaining the mechanism of catharsis, it is not to be understood that the cathartics can be used intravenously or even hypodermically, except in rare cases. Barium chlorid is very poisonous, and even a small amount of magnesium sulphate injected into the blood would prove fatal. Meltzer and Auer have recently stated that magnesium salts immediately inhibit intestinal peristalsis when they are injected into the vein of an animal. MacCallum's work, on the other hand, corroborates that of Claude Bernard, who found in 1857 that magnesium sulphate caused peristalsis when injected subcutaneously.

Among the curious theories advanced to explain catharsis is that of Groesbeck Walsh, who remarks that the actions of cathartics in general agree with bacterial action in the liquefaction of feces, in causing increased peristalsis and increased gas formation. Hence, he concludes that the cathartics act mainly by promoting bacterial activity. Even the action of calomel is thus explained, as it inhibits the growth of other bacteria, thereby promoting the rapid increase of the colon bacillus with the results just mentioned.

The use of purgatives is so general that it is usually considered a safe and harmless course, even when it does no good. This is true in the vast majority of cases, but Dr. M. L. Harris has recently called attention to the abuse of cathartics in conditions where they are potent for much harm. Among these he mentions: Closure of the intestine, as by strangulated hernia; complete local intestinal paralysis; localized spasmodic constriction, which tends toward spontaneous cure, but demands opium rather than cathartics; appendicitis and peritonitis, in which it is agreed that irritant cathartics, at least, are contraindicated, whatever the individual opinion may be in regard to the use of the salines.

Among the possibilities for direct harm it may be pointed out that when a portion of the intestinal tract is paralyzed, which may occur in ptomain poisoning, active cathartics might produce intussusception by driving the healthy contracted bowel into the paralyzed relaxed portion.

Classification of Cathartics.

There is a fairly sharp distinction to be drawn between the action of the irritant vegetable cathartics and the non-irritant salines. One class of the vegetable cathartics depends for the activity of its members on derivatives of anthracene, another class on the resin anhydrides. The preparations of the crude vegetable cathartics are usually but slightly soluble in water and dilute acids, but readily soluble in alkalis; they are, therefore, not absorbed from the stomach to any great extent, but, being soluble in the intestinal contents, they act by irritating the bowel, or by being in part absorbed. They are much slower than salines in their action, producing evacuation of the intestine only after from five to twenty-four hours with moderate doses. These facts are of much importance in choosing a purgative when there is inflammation of the intestine or other abdominal organs, as well as in pregnancy, since the irritation of the more drastic cathartics, by extending to the gravid uterus, may induce premature expulsion of the fetus.

Treatment of Constipation.

First in the treatment of constipation, for which purgatives are well-nigh universally employed, stands diet. By this means alone a very large proportion of cases of chronic constipation might be cured. It should contain a certain amount of indigestible residue, contrary to popular belief, and if the patient, in addition to correcting the diet, takes a fair amount of exercise in the open air and goes regularly to stool, but little purgative medicine will be needed.

The effect of stewed prunes and other fruits is too well known to require detailed mention; apples, figs and strawberries are equally useful. It should also be remembered that a glass of cold water, alone, taken on rising, will often act as a laxative.

Such simple remedies should always be tried before resorting to drugs in chronic constipation, since the habit of taking laxatives is easily formed, but not so easily dispensed with.

Hydragogue cathartics are sometimes used in dropsy and to relieve the kidney.

The excessive development of bacterial poisons in the intestine and their absorption into the blood cause symptoms varying from mere lassitude to profound shock. Purgatives sweep the bacteria and their poisons from the canal.

Diarrhea, due to the presence of irritating matter, such as undigested and fermenting food, is often promptly relieved by a saline purge. Saline purgatives are also useful in reducing fever, but they are not suited to cases of an asthenic type, because of the exhaustion which they produce.

We shall consider the more important of the official vegetable cathartics in this and the succeeding chapter, confining ourselves somewhat closely to their pharmacology, and in Chapter VIII we shall take up the salines, in connection with which we shall try to sound human credulity to its depths, with examples of the acme of impudent misrepresentation on the part of the makers of nostrums of the Epsom salt type.

The Anthracene Derivatives.

The vegetable cathartics of the first group which we shall discuss depend for their action on substances derived from anthracene. The graphic formula of this substance will help to show the relationship existing between several of these derivatives. Anthracene ($C_{14}H_{10}$) consists of three benzene rings united thus:

Tri-oxy-methyl-anthraquinone.

If an atom of H in the anthracene group is replaced by one of O, the compound is called anthraquinone or anthrachinone. Other atoms of H may then be replaced by OH and the compound is called oxyanthraquinone, a prefix to the *oxy* showing the number of such OH groups in the compound; thus the name tri-oxy-methyl-anthraquinone indicates that four H atoms of anthraquinone have been replaced, three by OH groups and one by a methyl group CH_3 . This compound is known as emodin.

Emodin is found in all the drugs which owe their activity to the anthracene derivatives, but its constitution may vary in the arrangement of the substituted OH groups in different plants. *Natal aloes* contains no emodin, hence it is not a purgative for man, but it is not found in commerce at the present time.

Other members of this group of cathartics contain other principles besides emodin, which are derived from the anthracene nucleus; thus chrysophanic acid, or di-oxy-methyl-anthraquinone, is also found in rhubarb, senna, rumex and probably in frangula. The name indicates that there are but two OH groups instead of three, as in the case of emodin.

Many other substances, the chemistry of which is obscure, are found in the cathartic drugs.

Preparations of the crude drugs contain colloidal matter which enhances the action of the pure principles, and they are therefore to be preferred to the latter; a fact to be remembered when reading the circulars of those nostrum makers who lay stress on their extraordinary facilities for supplying pure principles.

The drugs of the anthracene group are characterized by a mildly irritant action whereby they purge without producing inflammation, hence they are to be preferred to the resin anhydrides in chronic constipation, or when a strong irritant action is contraindicated.

ALOË.—U. S.—Aloes, including the Barbadoes, Curaçao, and the Socotrine, is the inspissated juice obtained from various species of aloes. It was known to the early Egyptians and Romans. One or more of the various species of aloes is official in every pharmacopeia. Natal aloes is now interesting only from a scientific point of view.

Average dose (of aloes): 0.25 gm. (4 grains).

ALOË PURIFICATA.—U. S.—This was made official in 1860, because of the impurities present in Socotrine aloes, due to the crude method of collection. The dose is the same as that of aloes.

ALOINUM.—U. S.—This is a neutral principle, varying in physical and chemical properties with the variety of aloes from which it is obtained. It does not fully represent the crude drug, medicinally.

Average dose: 0.05 gm. (1 grain).

EXTRACTUM ALOËS.—U. S.—This is the aqueous extract evaporated to dryness.

Average dose: 0.12 gm. (2 grains).

PILLULE ALOËS.—U. S.—Each pill contains 0.13 gm. (2 grains) of purified aloes and an equal amount of soap.

Average dose: 2 pills.

PILLULE LAXATIVE COMPOSITE.—U. S.—Each pill contains: Aloin, 0.013 gm. (1/5 grain); strychnin, 0.0005 gm. (1/125 grain); extract of belladonna, 0.008 gm. (1/8 grain); ipecac, 0.004 gm. (1/16 grain); and glycyrrhiza, 0.045 gm. (2/3 grain). This a substitute for the proprietary pills, which under a variety of names have attained a wide popularity.

Average dose (laxative): 1 pill.

The other official preparations into which aloes enters are: Pills of Aloes and Iron, Pills of Aloes and Mastie (the well-known Lady Webster's Dinner Pill), Pills of Aloes and Myrrh, Compound Pills of Rhubarb, Vegetable Cathartic Pills (no calomel), Compound Cathartic Pills, Tincture of Aloes, Tincture of Aloes and Myrrh, and Compound Tincture of Benzoïn. The last-named preparation does not contain enough aloes to make it useful as a laxative. Pills of Aloes are a convenient form of administration, the soap furnishing the alkali needed for developing the activity of aloes. The pill acts slowly and causes considerable pelvic congestion, hence it is useful in inducing delayed menstruation and increasing it if scanty. For the same reason it, more particularly than other members of the group, is contraindicated in fevers, pregnancy and in inflammatory conditions of the pelvic organs. Alone, it is not so useful in chronic constipation, but it is often added to other purgatives. The Compound Cathartic Pill is the most popular of these combinations.

Bile appears to increase the activity of aloes, and the formula given below is suggested as a suitable form of administration:

R. Aloë	
Fel bovis insp.	
Saponis	ââ gr. xx

M. Sig.: Make 15 pills, of which three are taken at a dose.

These may be coated with salol, to prevent their disintegration in the stomach. The coating is readily done by simply melting the salol in a shallow tin vessel, into which the pills are then dropped, and the vessel twirled until the salol solidifies. This method of coating is also applicable to other so-called enteric pills, which are intended to dissolve only in the intestine.

The Tincture of Aloes is so bitter that it is rarely used internally, but it is sometimes applied to bed sores and other local affections. Aloin alone is not so effective as aloes, but it is extremely popular in such combinations as the Compound Laxative Pill, which acts mildly after about sixteen hours.

SENNA.—U. S.—The Alexandria (short) and the Timnively, or Indian (long), senna are included in the official title. One, or both, of these is official in every pharmacopeia.

Average dose: 4 gms. (60 grains).

FLUIDEXTRACTUM SENNÆ.—U. S.—This is now directed to be made by first removing the resin with strong alcohol and subsequently extracting the drug with diluted alcohol.

Average dose: 2 c.c. (30 minims).

SYRUPUS SENNÆ.—U. S.—Syrup of Senna is now a very much more acceptable preparation than was that of the previous Pharmacopeia, and the physician should see that his patient gets the better article when it is prescribed.

It represents 25 per cent. of the fluidextract, from which the principle that causes griping has been removed with alcohol, with oil of coriander to flavor. It supplies an excellent substitute for the nostrums now becoming obsolete, which depend on senna for their activities, such as castoria and the various "fig syrups," so called.

For children one or two teaspoonfuls given alone at bedtime act as a gentle laxative; twice as much may be given as a cathartic. For adults twice as much is given as to children.

This preparation is not disagreeable to the taste, but since children are usually averse to anything called medicine, it may be given in a little cocoa.

Average dose (as laxative for children): 4 c.c. (1 fluidrachm).

PULVIS GLYCYRRHIZÆ COMPOSITUS.—U. S.—This powder, previously mentioned, contains 18 per cent. of Senna. It is widely used as a laxative.

CONFECTIO SENNÆ.—U. S.—This represents 10 per cent. of Senna, with cassia fistula, tamarind, prune and fig. It is substantially the same as the well-known proprietary medicine "Tamar-Indien."

Average dose: 4 gms. (60 grains).

INFUSUM SENNÆ COMPOSITUM.—U. S.—Formerly known as "black draught" (not black drop!). This represents 6 per cent. of senna, and 12 per cent. each of manna and magnesium sulphate, flavored with oil of fennel.

Average dose: 100 to 200 c.c. (3 to 6 fluid ounces).

The other only official preparation containing Senna is: The Compound Syrup of Sarsaparilla.

Senna is one of the best of remedies for chronic constipation, as its use does not entail a still greater tendency to that condition. It has the disadvantages of a disagreeable taste and of causing griping, if used alone; this tendency is overcome by combining it with aromatics. The confection is useful for children and in pregnancy. The milk of the nursing mother who takes Senna may purge the child. The resin which causes griping may be removed by extracting the leaves with alcohol without loss of the cathartic principle, the official fluidextract being made from Senna which has been thus treated.

The compound infusion or the confection may be used alone. The Compound Powder of Glycyrrhiza is an extremely popular laxative.

RHEUM.—U. S.—Rhubarb is obtained in Thibet and China from sources still undetermined. This valuable drug has probably been in use longer than any other substance now used wholly as a medicine.

Average dose: 1 gm. (15 grains).

The official preparations of Rhubarb are so numerous that we shall merely enumerate them, most of them being too well known to require extended notice. They are: The Extract, Fluidextract, Compound Pills, Compound Powder, Syrup, Aromatic Syrup, Tincture and Aromatic Tincture.

The average dose of either syrup is 8 c.c. (2 fluidrachms); of the tincture, 4 c.c. (1 fluidrachm); of the aromatic tincture, 2 c.c. (30 minims).

Rhubarb is useful in constipation associated with indigestion and catarrh of the small intestine, but not in chronic constipation, as the tannin present tends to increase the trouble after a time. All of the preparations are useful, but the aromatic syrup and the compound powder are probably the most popular, being especially useful in the summer diarrhea of children. The extract, the fluidextract and rhubarb in powder are all useful laxatives. The compound pills are said to be more useful in the expulsion of gas and in chronic constipation. They are very commonly given alone. The following has been much used, but it is largely empirical:

R. Extr. rhoi	
Ferri reducti, ââ.....	gr. lx
Arseni trioxid.,	
Strychnine sulph., ââ.....	gr. i
Quinine sulph.....	gr. lx

To be made into 40 pills; one to be taken before each meal.

RHAMNUS PURSHIANA.—U. S.—Caseara Sagra, or "sacred bark," is directed to be gathered a year before being used. It was introduced into medical practice in 1877, but as a domestic remedy in habitual constipation it was in use some time before that date in the region to which it is indigenous—the Pacific slope. It is now official in a number of pharmacopoeias. It is not given in substance.

FLUIDEXTRACTUM RHAMNI PURSHIANÆ.—U. S.—This is prepared with 40 per cent. alcohol.

Average dose: 1 c.c. (15 minims).

FLUIDEXTRACTUM RHAMNI PURSHIANÆ AROMATICUM.—U. S. The crude drug contains a bitter acid principle which is neutralized in this preparation with magnesia, orange and glycyrrhiza being added to flavor and sweeten it. There is no special skill required in making this preparation, and any reputable pharmacist can make it equally as well as the manufacturers who put it on the market in the form of proprietary preparations.

Average dose: 1 c.c. (15 minims).

EXTRACTUM RHAMNI PURSHIANÆ.—U. S.

Average dose: 0.25 gm. (4 grains).

Caseara sagra is probably the most useful laxative in the materia medica for chronic constipation. Unlike most of these remedies, which demand increasing doses, it improves the digestion, and the dose may be gradually diminished. Owing to the very disagreeable taste of the fluid extract, the aromatic fluid extract, or the extract, in pills or capsules, is to be preferred.

(To be continued.)

Clinical Reports

REPORT OF TWO CASES OF MALIGNANT ENDOCARDITIS.

JAMES F. PRESSLEY, M.D.
SAN FRANCISCO.

CASE 1.—F. D., boy, aged 16.

History.—Both of his parents are alive and well. The boy had always been well up to a month before entering St. Thomas Hospital. At that time he contracted an attack of gonorrhea and about a week later suffered from what was considered la grippe, with throat symptoms predominating. The illness which brought him to the hospital was diagnosed typhoid fever and was of about a week's duration. He had pains in his back and head, fever and delirium.

Examination.—Physical examination showed a well-developed and well-nourished boy. He was partly delirious and very apathetic. Pulse was 110, temperature 103.6. The eyes reacted to light and to accommodation. The tongue was flabby and coated. The lungs were negative.

Examination of the heart showed diffuse, forcible pulsation visible over the whole heart area, and more pronounced at the apex. This pulsation was also readily palpable. Percussion showed an enlarged heart area in all directions, especially downward and to the left. Auscultation revealed an extremely loud, harsh systolic murmur heard over all the heart area, but more distinctly at the apex. This murmur was transmitted to the left axilla and to the angle of the scapula. The pulmonic second sound was accentuated.

The spleen was greatly enlarged, tender and readily palpable. The liver extended downward to the level of the umbilicus and was tender on palpation. The abdomen was distended, painful and tympanitic. No roseola was seen. The left elbow was slightly swollen, red and tender. The urethra showed a purulent discharge containing gonococci. The reflexes were normal.

Course of the Disease.—During the two weeks the patient lived after his entrance to the hospital he was more or less delirious and sweated profusely. His pulse ranged from 90 to 110, and the temperature from 99 (almost normal) to 105.

Blood examinations showed 11,500 leucocytes, 4,000,000 reds, and 70 per cent. hemoglobin. Differential counts showed the number of polymorphonuclear neutrophils to be relatively largely increased. No plasmodia were seen. The Widal test was negative. The urine showed a large amount of albumin,

with hyaline and granular casts. The diazo reaction was negative.

Diagnosis.—The laboratory findings all seemed against the diagnosis of typhoid fever, so a diagnosis of malignant endocarditis was considered. It was difficult to say whether the endocarditis was due to a gonorrheal infection or whether the attack of la grippe was really rheumatic, with the chief symptoms showing in the throat. The fact that only one joint, the left elbow, was involved rather pointed to a gonorrheal origin.

Treatment.—The patient was given supportive treatment, and the usual remedies in endocarditis were administered, but without avail. The boy died about two weeks after his entrance to the hospital.

Autopsy.—A partial autopsy was allowed by his parents and this was performed by Dr. Philip King Brown.

The lungs were normal. The heart was greatly enlarged and softened and there were many fresh vegetations on the mitral valve. A small abscess was present near the base of the aorta. The spleen and kidneys both contained many septic infarcts. A small abscess was present in the prostate gland.

Cultures from the mitral valve, the base of the aorta, and the prostate showed a typical growth of the gonococcus of Neisser.

CASE 2.—Mrs. S. T., Italian, aged 35, was the mother of six children, and had had one miscarriage between the third and fourth child.

History.—The patient was always a large, healthy woman until two years ago, when she had an attack of acute articular rheumatism. From that time until five months ago, when her present trouble began, she had fainting attacks at irregular intervals. The present trouble began with an attack of right-sided pneumonia, since which she had lost weight and strength and had had daily attacks of sweating. Her appetite had been very poor and capricious. During these months she was treated for malaria.

Examination.—Physical examination at St. Thomas Hospital showed a thin, debilitated woman, very apathetic, complaining of pains in her head and limbs. Her appetite was poor and the bowels were constipated. Temperature was 101 and pulse 106. Inspection of the eyes showed pupils equal and sclera quite yellow. The tongue was clean. The lungs were normal.

Examination of the heart showed visible and palpable impulse over the precordial area, most pronounced at the mid-apex. The left border of the heart was just outside of the left clavicular line. A harsh mitral murmur at the apex was transmitted to the left axilla and to the angle of the scapula. The liver was not enlarged or tender. The spleen was not palpable or tender. The abdomen was not distended or tender, although the patient complained of pain about the umbilicus and in the epigastrium. There was no roseola. Nothing abnormal was found on vaginal or rectal examination. The reflexes were normal, and examination of sputum for tubercle bacilli was negative.

Blood examination showed white cells, 15,500, with a large relative increase of polymorphonuclear neutrophils; red cells, 4,100,000, and hemoglobin 70 per cent. No nucleated red cells or plasmodia were seen.

The urine contained granular casts, but no albumin. The diazo reaction was negative, as was the Widal test. The bowel movements were small and dark colored. No intestinal parasites or their ova were present.

Course of the Disease.—The patient kept getting gradually worse and had daily sweats and pain in head and limbs. Two days before death she developed a left-sided hemiplegia.

Diagnosis.—There being no other physical signs present but the enlarged heart and mitral murmur, and the blood findings and previous history of rheumatism and pneumonia pointing in that direction, a diagnosis of malignant endocarditis was made.

Typhoid fever was eliminated by the length of time she had been ill, the number of leucocytes, 15,500, and the absence of the diazo and Widal reactions. No tubercle bacilli being present in the sputum and no physical signs being present in the lungs, tuberculosis seemed unlikely. There was no wound or focus of infection discoverable, other than the heart, to ac-

count for a pyemia. Malaria could be excluded by the leucocyte count, the character of the cells and the absence of plasmodia. Uncinariasis was considered, but the absence of eosinophiles in the blood and of the ova of the parasite in the stools made this improbable. The development of the hemiplegia just before death strengthened the diagnosis of endocarditis, as the symptom was probably due to an embolus.

Autopsy.—A partial autopsy was obtained. This showed the lungs to be free from disease, except for some old adhesions of the right pleura to the chest wall. The heart was enlarged and both new and old vegetations were present at the mitral valve, one of the new ones being as large as a white bean. The abdominal organs were normal and no latent gallstones were present in the gall bladder.

Cultures from the mitral valve were taken. These were examined by Dr. Harold Brunn in the laboratory of the medical department of the University of California and a pure growth of pneumococcus was found.

A REMEDY FOR CHOLERA.

REV. CLARENCE D. USSHER, M.D.

VAN, TURKEY, ASIA.

Recently I picked up a piece of paper, apparently cut from some medical journal for the purpose of reinforcing a binding, and my eye caught the statement, by some one who apparently wrote as an authority, that "until now no remedy for cholera has been discovered," "all bad cases die [*sic*], in spite of remedies." The writer also expressed the opinion that the patients who recover would recover without medicine. About the same time I learned that cholera was spreading in Europe and that there was panic in places.

These things lead me to feel that I have been remiss in my duty as a physician in not putting definitely before the profession the results of treatment of cholera in Van during an epidemic of six weeks' or more duration in the early part of this year.

As the only foreign physician within a week's journey in any direction, my duties are heavy and prevent me from making a scientific report or even keeping satisfactory records of the numerous cases seen. I wish simply to report a fact and to let others work out details for themselves.

I claim no credit as discoverer of the remedy, nor for its application. Koch of Berlin discovered that "quinin in solution of from 1,1000 to 1/2500 would kill the cholera germ in from ten to thirty minutes." This was applied by Graham and reported by E. B. Fullerton¹ of Columbus, Ohio, from whose report I obtained my suggestion. I wish to corroborate the statements made there and to say that cholera has lost its horrors here through the use of quinin sulphate (or bisulphate, preferably the sulphate) in ten-grain doses every hour till bile reappears in stools; from forty to eighty grains have been given. The quinin is not absorbed, but acts in the intestines. Aromatic sulphuric acid lemonade proved a satisfactory prophylactic. Sulphate of copper, 1 to 100,000, for drinking and washing purposes stopped the disease and stamped out the epidemic in the military barracks where hundreds had died.

With quinin, more than 90 per cent. of the patients recovered, including those brought to our hospital moribund.

With the old lines of treatment, every patient during the first week succumbed, testifying to the virulence of the epidemic. Saturday night at midnight I learned of the new remedy, and after that lost but two patients seen before they were moribund.

Our hospital treatment consisted of the following: Quinin sulphate, gr. 10, every hour till rice-water stools ceased and bile reappeared; sweet spirits of niter, dry cupping heat and friction for suppression of urine; saline injections when the wrist pulse had disappeared (but some patients in this condition recovered under quinin treatment without injections). Occasionally a diarrhea mixture was used when intestinal activity was excessive after the reappearance of bile in the stools. Where irritability with foul odor persisted, five grains of a mixture of equal parts of the sulphophenolates of zinc,

calcium and sodium were given at intervals of from two to four hours.

I am so fully persuaded that quinin is nearly a specific for cholera that I feel it my duty to ask you to give this as wide publicity as possible.

A Columbus physician has criticised missionary physicians for not giving the world more benefit from their necessarily large experience. For my part I must confess that my seclusion here for eight years makes me diffident about putting my humble thoughts before my more scientific brethren who have kept abreast of the times.

EPIGASTRIC MURMUR CAUSED BY A DISPLACED DISTENDED GALL BLADDER.

C. M. COOPER, M.B., M.R.C.S.

SAN FRANCISCO.

Epigastric murmurs are well known to be of both intra-vascular and extravascular origin. Thus any tumor which lie over the artery, e. g., a pyloric or pancreatic carcinoma may press on this vessel and give rise to systolic murmur or to a marked visible localized pulsation. Hence it has become a well-recognized clinical custom to examine patients who present localized pulsations and murmurs of doubtful origin in the knee-chest position. I wish, however, to report a case in which localized pulsation which was actually expansive, together with a systolic bruit, were present in the epigastric region, these signs being due to a distended, displaced gall bladder. The key to the diagnosis lay in the disappearance and reappearance of these signs coincident with the partial emptying and refilling of the cystic swelling. Operation demonstrated the mesial position of the gall bladder. After operation the murmur disappeared, and an autopsy some months later showed an absence of any arterial abnormality. Such a case suggests that we should not only examine these patients in the knee-chest position, but also in the right and left lateral postures so that the falling back of displaced organs into their original lateral position may be favored and thus elimination be made more comprehensive. Systolic murmurs, of course, have been long known to occur in association with attacks of acute cholecystitis, as do friction murmurs, and probably too little attention is paid to these diagnostic auscultatory phenomena, but it is not in such a category that the above mentioned case belongs. I have notes of a somewhat similar case, in which, however, the diagnosis was not confirmed by operation or autopsy, and hence, though very suggestive, is unreportable. The co-existence of gall bladder disease with a murmur due to another cause not infrequently occurs. The adoption of the right and left lateral postures will, I believe, aid in the diagnosis.

ADAMS-STOKES' DISEASE.

E. SCHMOLL, M.D.

SAN FRANCISCO.

A case of Adams-Stokes' disease which I had the opportunity to observe presented symptoms of heart block. There were from three to four auricular contractions to one ventricular beat. During the attacks the ventricle stopped entirely, while the auricular rhythm kept on undisturbed. The patient died after twenty-four hours.

In view of the experimental work on heart block done by Erlanger and Hering I felt justified in diagnosing a lesion of the auriculo-ventricular bundle of His.

The postmortem was limited to the heart. Macroscopically no lesion could be detected, but the microscopic examination by Dr. Ophüls showed scar formation in and around the bundle of His just below the membranous septum.

AN ADVANCE IN CYTOTOXIC STUDIES.

When in 1899 v. Dungern found that a specific immunity could be obtained against epithelial cells, and suggested the possibility that in this direction might be sought an immune serum against cancer, intense interest was immediately awakened in the subject of cellular toxic serum. The simplicity of the method of investigation attracted many to the work, for all that was necessary was to inject an emulsion of the cells to be studied into the peritoneal cavity of a laboratory animal, obtain the blood serum of the animal after it had been injected several times, and inject the serum thus obtained into normal animals of the same species as the one that had furnished the original cells. Within a few months the literature teemed with more or less hasty reports of the discovery of serum toxic for nearly every cell in the body. Animals injected with serum of animals immunized against kidney tissue were found to develop renal lesions, and so the serum was said to be nephrotoxic; similarly hepatotoxic, cardiotoxic, neurotoxic, thyrotoxic, and every other organ and tissue toxic serum was described.

Most of the first reporters described the serum as specific for the organ used in the immunizing, but soon it began to be noted that this specificity was at the best quantitative; that is, the organ against which immunity was sought was most affected, although other organs might also show more or less degeneration. In some reports the type of organ furnishing the injected cells was even less affected by the immune serum than some of the other organs, particularly the liver and kidney. Furthermore, the immune serum was found to contain substances agglutinating red corpuscles; and agglutinated red corpuscles, by plugging up capillaries, are capable of causing much degeneration in many organs and tissues of the body. Finally it became clear that injections of ground-up organs did not produce a specific immunity against the chief cells of that organ, even when the precaution was taken first to wash out the blood. The work of Pearce was particularly conclusive in this respect, showing that immunity against specific cells is difficult or impossible of attainment. Because of these unsatisfactory results interest in cytotoxic serums has waned, in spite of the great importance that the work would have if it were successful.

A new method of attacking the problem has been devised by Beebe,¹ which offers hope of greater success.

Beebe isolated from a number of organs the nucleoproteids (kidney, liver and pancreas) and immunized rabbits against them. The serum so obtained, when injected into dogs, was found to possess a much greater degree of specificity than has been obtained by immunizing with the organ emulsions. Serum of animals immunized against kidney nucleoproteids caused severe renal changes both in the structure and function of the organ, being fatal in a few days, and did not affect the liver. Immune serum for liver nucleoproteids caused severe hepatic changes and was almost without effect on the kidneys. Antiserum for pancreas nucleoprotein seemed to be equally specific.

The explanation of these successful experiments may be as follows: Every cell contains a number of proteids, of which the nucleoproteids are probably the most important and in many cells the most abundant. The other proteids are considered by many physiologists as largely adventitious, chiefly existing as food stuffs or as intermediary steps in the formation and destruction of the more complicated nucleoproteids. Furthermore, the nucleoproteids are probably the most specific constituents of the cells. The other cell proteids, as well as the carbohydrates and lipoids, are, so far as our imperfect knowledge of cell chemistry permits us to judge, much the same in the cells of different organs, but the nucleoproteids of different organs show quite distinct differences in composition, great enough to be detected by the relatively crude methods at our disposal. By using the nucleoproteids of an organ, therefore, we secure the specific ingredients and reject the nonspecific, an important step in seeking for specific cytotoxins.

The chief criticism that can be made of Beebe's work is the relatively small number of experiments, five with nephrotoxin, three with hepatotoxin, two with pancreatotoxin; a criticism that will undoubtedly soon be met with a report of further investigations of this important subject.

THE TREATMENT OF TUBERCULOSIS BY TUBERCULIN.

Recently¹ we called attention to the views of A. E. Wright of London regarding the treatment of diseases due to endotoxic bacteria by means of vaccines. In a recent article Wright² gives his latest views regarding this method of treatment and refers to his results in tuberculosis.

It will be remembered that Wright's method of administering bacterial vaccines, i. e., sterilized and standardized suspensions of micro-organisms, based on the fact that in bacterial diseases there are times when the body resistance is lower than normal, and times when it is higher. Wright measures the resistance to the particular infecting germ, in tuberculosis, for example, to the tubercle bacillus, by submitting a standardized culture of the organism to the action of the living leucocytes of the individual whose blood he is testing. The partic-

1. THE JOURNAL, December 23, 1905.

2. THE LANCET, 1905, vol. II, p. 1598.

ular antibacterial element measured by Wright's method is one which injures the bacteria so that they can be taken up by the leucocytes. Wright speaks of it as the opsonin. It is found that in a healthy individual the leucocytes will take up a certain number of bacteria, and this number is approximately the same in all healthy human beings. One whose leucocytes take up a number of bacteria corresponding to the number taken up by the leucocytes of a healthy person is said to have a normal opsonic index, and in disease the opsonic index may be either above or below normal. The fundamental principle underlying Wright's method is that bacterial vaccines must be administered only when the opsonic index is above normal, or, more correctly, when two tests taken at intervals have shown that the opsonic index is rising. If the vaccines are given when the opsonic index is falling they do harm rather than good.

In discussing the principles which ought to regulate the dosage of bacterial vaccines Wright calls attention to some fallacies which have become engrafted on the medical mind. One of these is the idea that in order to secure the greatest yield of protective substance it is necessary to give enough vaccine to produce a constitutional reaction of a marked character. Wright shows that this is not so at all, that just as good, and sometimes better, results are secured by small doses, and the patient is thus saved much discomfort. In tuberculosis Wright employs the new tuberculin in doses corresponding to from one-thousandth to one-six-hundredth of a milligram of tubercle powder and with perfectly satisfactory results. It seems quite certain that the mechanism which leads to the formation of antibacterial bodies is one which is easily stimulated, and it is very likely that it is possible to overstimulate it. The correctness of the dosage may be measured by testing the opsonic index, which shows a tendency to remain low longer than usual during the negative phase when too large doses are being given.

In discussing the manner of reaction of the organism in infections Wright makes a sharp distinction between general and local infections. Local infections, like lupus, for instance, tend to last for years, and he suggests that this may be because the bacteria causing them do not escape into the blood and give rise to the formation of antibacterial bodies, and because their situation places them in a position unfavorable to the action on them of such antibacterial bodies as may be present in the blood at the time the infection originated or during its course. In general infections, on the other hand, bacteria escape into the blood intermittently, but they do not always escape at a favorable time. If they escape during the time that the opsonic index is on the rise they, of course, do good, but if they escape during a period of fall in the opsonic index they may prove fatal. In discussing local infections it is also pointed out that the conditions are often unfavorable to the free circulation of lymph through the infected area, and, as the lymph carries the antibacterial bodies, this is a protec-

tion to the bacteria. It is to be noted that many of the old remedies for infection, based on empiricism, are agents which tend to increase the lymph circulation in the affected area. It is also to be noted that the surgical removal of an infected area, no matter how radical the operation, probably never removes all the nidus of infection, but it places whatever bacteria are left in a position in which they can be reached by the lymph circulation, and Nature completes what the surgeon began.

The results reported by Wright from his treatment of certain forms of tuberculosis are highly encouraging. The method has not been extensively tried in all forms of the disease, in lung tuberculosis, for example, but its use in these cases will doubtless follow. The most encouraging results followed the treatment of tuberculosis of the subcutaneous tissues and bone and tuberculosis of the lymph nodes. In the case of the former variety Wright reports so far uniform success, and the cases in which a cure was effected were those which had defied all other methods of treatment. The treatment of tuberculous lymph nodes was so successful that Wright predicts the abandonment of surgical and climatic methods in favor of tuberculin. Wright's methods have been slowly, but apparently surely, attracting more and more attention. We have seen appear in the past fifteen years not a few loudly heralded treatments for tuberculosis, only later to see them disappear discredited. Let us hope that at last we are on the right track.

A BILL TO PREVENT FRAUDS IN "PATENT MEDICINES."

A campaign of education against fraud and deception in the patent medicine business has been conducted by certain lay journals—principally *Collier's Weekly* and the *Ladies' Home Journal*—and the public's attention has been called, as never before, to the dangerous and fraudulent character of the majority of these preparations. The public is aroused; there is no doubt of this. But the public is made up of individuals and, as is usually the case, each individual waits for another to act. The *Ladies' Home Journal* seems to have recognized this fact and, having educated its readers to the point where they realize something should be done, proposes certain legislation and gives them a chance to do something. The February issue contains a bill for an act to be introduced into every state legislature that meets this winter. The bill which we reproduce on page 373 bears evidence of careful thought, and, while it is not perfect, it is as nearly so as we may hope to get one that can become a law in our legislatures.¹ "This is not a bill," Mr. Bok says, "of our individual drafting or of our own personal approval. It has been submitted and carefully gone over by the most distinguished and conscientious representatives of the law, of medicine and of the drug trade in this country. It is not a one-sided affair. It is not aimed to injure, but to protect. We

1. Bills to regulate the sale of "patent medicines" are now in three legislatures—Kentucky, Mississippi and New York.

have the best of reasons for believing and saying that the provisions of this bill will not be objectionable to those manufacturers of 'patent medicines' who have really an honest article and who are not afraid of putting the contents of their medicines on the label of each bottle. The honest men engaged in the 'patent-medicine' business are just as anxious as we are or any one else to stop the deceit and trickery running wild in their trade."

Mr. Bok devotes a page to a personal appeal to his readers to act, and undoubtedly many of them will respond, for, besides this, other matter appears in the current number of his journal, not the least important of which is a contribution by Mark Sullivan, who wrote the unsigned article in *Collier's* on "The Patent Medicine Conspiracy Against the Freedom of the Press." In the present article Mr. Sullivan tells us "How the Game of Free Medical Advice Is Worked."

Physicians are appealed to: "I would also ask the hundreds of physicians and medical associations, who have written to this magazine, to lend their attention and support to this legislation. With a very few exceptions, physicians and medical bodies all through the country have been singularly lax and remiss to the 'patent-medicine' measures which have come up before the state legislatures. Whatever may have been the causes for this remissness, it is now distinctly the part of every physician, and the organization to which he belongs, to take an active part in making this legislation possible and effective, so that legislators can no longer wonder at the absence of the medical profession at the hearings given these bills."

And this brings us to the point. What are we going to do about it? Shall we assist in this movement? No one knows so well as the physician the havoc caused by self-dosing on the part of the public. He sees, as no one else sees, the physical harm that results from the continual taking of, for instance, cathartic medicines, whether it be in the form of pills or "blood purifiers." He knows, as no one else knows, that taking such medicines produces the very ills they are supposed to cure; that nine out of ten cases of chronic constipation—the cause of so many minor ailments—are the ultimate result of the continual use of cathartics. The physician knows, as does no one else, the harm resulting from the indiscriminate use of medicines containing opiates of various kinds; that soothing syrups, nerve sedatives and acetanilid mixtures, if used without due regard to their possible injurious effects, are liable to wreck, and do wreck, the constitution alike of the healthy infant and of the robust man and woman. Medicines containing alcohol, the "bracers," have the same temporary effect and ultimate results as whisky, and everybody knows this as well as the physician, but everybody does not know, as he does, how large a number of the "patent medicines" belong to this class. No one knows as well as the physician that many of the ills for which "patent medicines" are taken are imaginary ones caused

by reading patent-medicine advertisements. And, most important of all, no one knows as does the family physician how many anxious wives, husbands, mothers and fathers use money to buy a fraudulent "patent medicine" for one they love when they need it to buy bread—because, in their desperate anxiety, they are ready to grasp at any proverbial straw, and the straw offers itself in the lying advertisements of the nostrum vendors.

We know that people are being swindled by "patent medicine" promoters as by no other class. We know that the taking of these nostrums is injurious, in many instances to a serious degree, and we know that the business unregulated is against public health as well as against public morals. As physicians we know all this by actual observation and by personal knowledge of definite instances, and as no others can. Is it, then, not our duty to fight these frauds? Suppose the "patent medicine" men's association and their mouthpieces do say that we are acting for selfish motives. What of it? We know that we are not, and the intelligent public knows it. In any event, as we showed last week, they are accusing us of instigating the fight, and we might as well deserve the vituperation of these nostrum men, since we get it anyway. In reality, there would be some apparent justification for saying that we are encouraging the use of "patent medicines" for selfish purposes, because, as Dr. G. A. Syme said in his address before the Australian Medical Congress last fall, the taking of "patent medicines" makes work for physicians, and, therefore, from a commercial point of view, it would be better for us if the "patent-medicine" men were given full sway.

The legislation asked for is not against "patent medicines" *per se*, but against the fraud and deception connected with them. Some of us might think that there should be no medicines sold direct to the public. This would be ideal in the minds of some, but, though ideal, it would not be practical. Further, there is no reason why an individual should not have the right to buy a cough syrup, a box of cathartic pills, a grain or an ounce of quinin, or any non-poisonous medicines. It is not worth while to strive for an impossible ideal—the prevention of the sale of medicines to the public; but it is worth while to strive for the possible. And a law to compel the manufacturers of medicines to state plainly what they contain is a possibility. Such a law is needed for the public good, and it seems to us that it is our duty to try to get such laws passed in every state in the union, and then we should educate the public to understand the harm that lies in those preparations that contain dangerous drugs.

These are the principles on which we must carry on the propaganda—absolute non-secrecy regarding the composition of the preparations and the truth regarding their effect on those that take them. Such a platform is sane, can not be attacked, and will receive the support of the public and of most of the newspapers, in spite of the fact that they would sacrifice some of their income

by giving such support. Of course, such a platform means a campaign of education lasting for years, in which we must take the lead, but in which we would have the support of the largest part of the public.

LIVING TYPHOID CENTERS.

An enthusiastic sanitary engineer is said to have remarked a few years ago that if all public supplies of drinking water could be obtained from unpolluted sources or purified by sand filtration, typhoid fever would soon become extinct. Far be it from us to decry the importance of infected water in disseminating typhoid fever, or to cause less stress to be laid on the sand filtration of municipal water supplies. No one with an understanding of the facts can doubt that during the last few decades contaminated water has been the chief means by which this insidious disease has been kept alive and distributed to widening circles in all civilized countries. The recent improvements in the quality of water supplies—a matter in which to our humiliation the United States still lags behind the leading countries of Europe—have had the secondary effect of directing attention to the existence of other important sources of typhoid infection. We have taken occasion in these columns to emphasize more than once the rôle played by close association or contact of the sick with the well.¹ At least one extensive epidemic—that at Winnipeg, Manitoba, in 1904-5—and many minor ones have been shown to be due principally to spread of the disease from case to case. The investigations conducted by the German government into the modes of occurrence and spread of typhoid fever in rural districts in Germany have done much to establish the frequency of cases due to contact. In connection with these investigations, a recent article by Lentz² serves to bring into relief a source of infection that is likely to prove especially difficult to evaluate and combat. It has been known for some time that typhoid bacilli in some cases might persist in the excretions of typhoid patients far into convalescence; Lentz has now brought to light the existence of a class of persons whom he calls "chronic carriers of typhoid bacilli." It appears from his researches that a certain proportion of typhoid-fever patients—a proportion that may be as high as 4 per cent.—carry living typhoid bacilli about with them for years after complete recovery from the disease. In one case examined by Lentz, typhoid bacilli were found in the excreta fifteen years after the attack, and were present during a period of two and one-half months when the observations were made. In another case bacilli were found in every examination (thirteen) made at intervals for twelve and one-half months after the attack. A history of the infection of associates by these chronic bearers of bacilli was obtained in some instances. A particularly serious aspect of this matter appears in the difficulty of disinfecting these living ty-

phoid centers. All the attempts made by Lentz to rid these "microbe bearers" of the typhoid or paratyphoid bacilli that they harbored signally failed, although a great variety of drugs were administered for the purpose. For the present there would seem to be little that can be done to obviate the menace of these microbe bearers to the community. The surveillance and bacteriologic control of such cases, although possibly desirable in a community endowed with the Prussian police system, is rather chimerical for less efficiently organized peoples.

CHRONIC ACETANILID POISONING.

That chronic poisoning from acetanilid is not uncommon is evident from the numerous cases that have been reported recently. In this issue is the report of a case by Herrick and Irons, in which the absorption of the drug was from an ulcer of the leg, to which the remedy had been applied almost daily for seven years for its analgesic effect. In this respect this case is a rarity, but it warns us that care should be exercised in the use of this drug in dermatology or as an antiseptic in surgery. Points of interest in connection with the chemistry of the urine in chronic acetanilid intoxication are also referred to in the article, but what is of most value, at least to the general practitioner, is the grouping together of the phenomena of this form of poisoning, making of it something like a clinical entity.

According to Herrick, the acetanilid habit is to be suspected in a patient who presents a secondary anemia, cyanosis, dyspnea, nervousness or gastrointestinal disturbance without an adequate explanation for it in heart, lungs or other organs. Splenic enlargement is not uncommon. The crucial test is the examination of the urine. This is commonly dark in color, it darkens still more on standing and contains an increased amount of conjugate sulphates and also paramidophenol. The general practitioner, although he may not be a chemist, need not feel that the examination of the urine in such cases is beyond him, for, as will be seen by consulting this article, the test for paramidophenol is simple.

If some of the obscure cases of neurasthenia, anemia, dyspepsia, etc., were more carefully examined, we believe an explanation for them would not infrequently be found in the acetanilid habit, the drug being taken either as such or as one of the ingredients of the many headache remedies and painkillers so easily obtainable at the drug store, and so often prescribed unknowingly by physicians.

The reports of such cases can not fail to have a wholesome influence. They stimulate to greater thoroughness in ferreting out the existence of this habit, lead to greater caution in the prescribing of this remedy, which, when improperly used, is so potent for evil, and encourage us all in our efforts to combat the manufacture, sale and use of the many nostrums that contain this really dangerous drug.

CHICAGO HEALTH DEPARTMENT AND PURE-FOOD
LEGISLATION.

"The Chicago Health Department might well be engaged in better business than casting slurs, directly or indirectly, at the agitation for pure-food legislation." Such is the opening paragraph of an editorial in the *Chicago Record-Herald*, January 30. It is called forth by a statement in the *Weekly Bulletin* of the Chicago Health Department. The *Bulletin*, commenting on food adulteration, says: "The steadily increasing healthfulness of Chicago—which is alleged to be the head center of the nefarious industry—does not warrant the recent sensational statement that 'thousands' of people, instead of being nourished by what they eat, are slowly done to death by it." As the *Record-Herald* says, whatever exaggeration there may be in the statement quoted, certainly Chicago health statistics do not prove anything either for or against it. "Upward of 25,000 people die annually in Chicago alone, and certainly 'thousands' could die annually in the whole country from the indirect evil effects of impure food, without making any impression on the Chicago statistics which could be directly traced." It might be suggested to the health department that adulterated foods do not necessarily kill, even though the substances used may be poisonous in character, but that they do result in injury to health. While we are not here discussing the pure-food bill, it should be remembered that the bill is not only against poisonous adulteration, but it is against any adulteration, misbranding or deception. It is rather strange for a city health board to go out of its way to aid those who are fighting legislation in the interest of health and honesty, even though some of that city's business interests may be injured if such legislation is enacted. As the *Record-Herald* says, "The harmfulness of many kinds of adulterations has been proved repeatedly by scientific tests. The people who consume the adulterated goods have no means of protecting themselves, or, rather, they have no means except through common action in their state or national governments. They must be protected by law. The argument for a pure-food law goes, however, even deeper than this. It is at bottom an argument for the 'square deal' in the food industries. 'Honest labels' is a keynote of the proposed legislation. There is not nearly so big a trace of hysterics in the agitation for the reform as there is in the health department's unfriendly comment." We might suggest to the health department that there is one point to which they never call attention in making up their statistics, and that is that Chicago is a comparatively young city, that it has been growing rapidly during the last two or three decades—especially during the last ten or fifteen years—and that this growth is made up of young, vigorous, healthy people whose normal death rate ought to be low. We have no statistics at hand to prove the assertion, but no one will deny that Chicago has comparatively very few old people, and, consequently, that natural death from old age is very much less than in older communities. This comment of ours certainly has as much logical relation to the subject as the uncalled-for comment of the Chicago Department of Health concerning impure food.

SENSIBLE SANITARY MEASURES ON THE ISTHMUS.

For the steady progress in bettering health conditions at the Isthmus, Colonel Gorgas deserves great credit. On January 16, he reported that there was no quarantinable disease of any kind. During December there was but one case of yellow fever on the Isthmus. The morbidity continued very low, the rate being 19 to the 1,000. The heaviest death rate was due to pneumonia among the negroes, who do not use the precautions that white men exercise. The excellent report is an effective answer to the recent severe criticisms by Poultney Bigelow in the *Independent*. This correspondent criticized the insanitary location of Colon over a swamp, the poor houses, poor arrangements for disposing of night soil, etc., and called attention to the "absurd" system of sanitation which pays so much attention to mosquito work and fumigation. In reply to all such criticisms, Colonel Gorgas simply calls attention to the fact that the Sanitary Department on the Isthmus was not established to demonstrate any theory of disease. "We came for a practicable purpose," he says, "to decrease disease as much as possible. The 'absurd measures' have certainly so far accomplished this result. The facts stand forth that at present we have not a single case of yellow fever on the Isthmus, and during the whole month of December had only one; that malaria has been brought so well under control that our total sick rate is as small as that of any considerable body of men working anywhere in the United States. This writer, Mr. Bigelow, judges us by a sanitary standard of ten years ago and as applied to the temperate zones. He is apparently unaware that recently acquired knowledge has entirely revolutionized tropical sanitation. Our knowledge and experience in tropical sanitation have shown us that if every house in Colon had been supplied with modern plumbing and the buildings themselves had been well-built Philadelphia cottages, and we at the same time had had uncovered cisterns and water barrels, we would by this time have lost half our non-immune force from yellow fever. But if we look after the cisterns and water barrels and take the appropriate measures with regard to the sick from yellow fever, it is of very little importance whether we have a modern water closet or the more primitive pit." Colonel Gorgas goes on to say that what they are after is to get rid of yellow fever and to make the Isthmus inhabitable. In this he is certainly succeeding.

LIFE-SAVING PRECAUTIONS AGAINST THEATER FIRES.

Following the terrible Iroquois theater fire in Chicago, we commented on the experimental theater which was prepared in Vienna to test various safety devices. Consul-General Rublee of Vienna has just made a report on the tests made with this model. As nearly as possible exact reproductions were made of the conditions existing in actual theaters and old theatrical scenery and hangings were used, saturated with kerosene. Some of the conclusions were as follows: The most effective means of reducing the danger to the audience is to provide means for the escape of the dangerous gases and smoke through ventilators on the roof of the stage. When ventilators of sufficient size were opened, automatically or

otherwise, the fire was, to a great extent, confined to the stage, and a draft was caused from the audience room onto the stage, but when the ventilators were closed the auditorium was filled with gases, smoke and flames so speedily that the lives of many spectators would be imperiled. Further, in the latter case, the movement of the iron curtain was frequently interfered with by the pressure of gases from the stage so that it proved inadequate for protection. This latter point seems to us a very important one, in view of the great dependence now placed on the steel curtains. If a severe fire would cause this curtain to bind, or would otherwise prevent its descending promptly, another terrible fire may result, because the use of inflammable scenery has not been discontinued. These experiments further revealed the striking fact that when the ventilators were covered by wire screens the charred paper, fragments of scenery, etc., carried up by the draught, lodged against these wire screens and, to a greater or less extent, closed them, thus rendering the ventilators valueless. In this connection attention is called to the building law of New York City, which requires that underneath all of these smoke vents wire netting must be stretched. These points become very important when one realizes their relation to the present provisions in theaters in the United States.

Medical News

ILLINOIS.

Births Double Deaths.—The annual report of the State Board of Health shows about 65,000 deaths and 150,000 births in Illinois during 1905. The males born exceeded the females by about 6,000.

Winnebago County Election.—At the annual meeting of the Winnebago County Medical Society, held in Rockford, January 9, Dr. Thomas H. Cullhane was elected president; Dr. Robert C. Bourland, vice-president, and Dr. William E. Park, secretary and treasurer, all of Rockford.

State Board of Health.—At the twenty-ninth annual meeting of the State Board of Health, held at Springfield, January 25, the following officers were elected: Dr. George W. Webster, Chicago, president, and Dr. James A. Egan, Springfield, secretary and treasurer. Dr. Egan succeeds Dr. Peter H. Wesel, Moline, as treasurer.

Personal.—Dr. Mills F. Clark, assistant at the Illinois Hospital for the Insane, Elgin, has resigned and will settle in Massachusetts. —Dr. and Mrs. James W. Pettit, Ottawa, have gone to Texas for a visit. —Dr. Patrick H. Kelly, Chillihothe, was thrown from his buggy, January 19, dislocating his right arm at the elbow. —Dr. and Mrs. Matthew M. Hill, Taylorville, are recovering from a severe attack of ptomain poisoning.

Communicable Diseases.—Three cases of smallpox were discovered at the Illinois Central Hospital for the Insane, Jacksonville, January 27. Vaccination of the 1,200 inmates and 500 employes has been ordered and strict quarantine has been instituted. —Suspected smallpox has caused the State Board of Health to send an inspector to Hillsboro, Granite City and Venice. —Bloomington now has 10 families under quarantine for diphtheria.

Chicago.

Kirmess Nets Thousands.—The Cribbside Kirmess realized about \$25,000 for the Children's Hospital.

Personal.—Dr. David J. Doherty leaves for Manila, via Spain, February 20. —Dr. Henry W. Cheney and family have left for Vienna. —Dr. and Mrs. W. J. Class have reached Padueah, en route by gasoline launch to Chattanooga. —Dr. Harrison L. Mettler has resigned as medical inspector of the Department of Health.

Deaths of the Week.—The 504 deaths reported are 107 fewer

than those of the previous week and 51 fewer than those of the corresponding week of 1905. On the basis of population the annual rate of the week is 16.7, and 12.2 per cent. lower than for the previous week and for the corresponding week of last year respectively. Bright's disease, 4 less; bronchitis, 10 less; consumption, 8 less; cancer, 14 less; heart disease, 8 less; influenza, 3 less; pneumonia, 25 less, and scarlet fever, 2 less, are among the important causes of death showing gratifying reductions. Only diphtheria, 6 more; acute intestinal diseases, 8 more; scarlet fever, 1, and typhoid fever, 2 more, show any increase. The death rate was equivalent to 12.82 per 1,000. Pneumonia caused 86 deaths and consumption 61.

INDIANA.

Beaven Again Fined.—Leslie Beaven, an osteopath of Vincennes, who was arrested several months ago, tried and convicted of practicing medicine without a license and fined, was again tried for a similar offense in the Daviess County Court at Washington, January 12, and fined \$25 and costs.

Memorial Hospital Staff.—At the annual meeting of the trustees of Reid Memorial Hospital, Richmond, the following medical staff was named: Drs. George H. Grant, David W. Stevenson, Allan L. Brankamp, Charles S. Bond, Melville F. Johnston, Harry H. Weist, John M. Wampler, Isaac S. Harold, Stephen C. Markley, Joseph M. Bulla, Charles Marvel, T. Henry Davis and Joseph M. Thurston.

A Nonagenarian.—Dr. William H. Wishard, Indianapolis, celebrated his ninetieth birthday anniversary January 17. An informal reception was given which was attended by many members of the Indianapolis Medical Society. Dr. Wishard is one of the two surviving charter members of the State Medical Society. At the meeting of the society January 16 Dr. Frederick C. Heath, on behalf of Dr. William N. Wishard and other members of the family, presented an oil painting of the venerable physician to the society. On the evening of January 17 the family of Dr. Wishard gave a dinner to members of the profession and friends, at which about seventy were present.

Personal.—Dr. Albert H. Combs, Marion, has recovered from his recent illness. —Dr. and Mrs. Leo J. Weinstein, Terre Haute, have gone to Fort Collins, Colo., for six or eight weeks. —Dr. Schuyler F. Teaford, Paoli, has been appointed physician of Orange County. —Dr. Benjamin F. Whitmer, Goshen, expects to spend the winter in Pensacola, Fla. —Dr. Marcus H. Thomas, Huntington, sprained his knee while skating January 12. —Dr. S. K. Houser, Converse, has been reappointed health officer. —Dr. Guilford A. Mottier, Richmond, had a narrow escape January 6, when his buggy was struck by a switching freight train and demolished. —Dr. Charles Trueblood, Anderson, left for Oklahoma and New Mexico, January 14. —Dr. Thomas R. Barker has been appointed health officer of Danville. —Dr. Patrick G. Carlisle, Connersville, received severe scalp wounds during a windstorm January 15, when a large curved plate-glass window was blown from the fourth floor to the pavement, striking him as it fell. —Dr. A. P. Fitch, Lebanon, is seriously ill.

December Disease and Death.—Bronchitis and tonsillitis were almost equally prevalent in December and led the list of diseases. Pneumonia increased greatly over November. This is also true of influenza and rheumatism. Typhoid fever fell to fifth place in its area of prevalence. There were reported 112 cases of smallpox in 13 counties, with 1 death. In the corresponding month of last year there were 472 cases reported in 38 counties, with 8 deaths. Typhoid fever was reported in 53 counties. There were 2,657 deaths, corresponding to an annual death rate of 11.8 per 1,000. Certain important causes of death were as follows: Consumption, 336; typhoid fever, 66; diphtheria, 58; scarlet fever, 7; whooping cough, 9; pneumonia, 347; diarrheal diseases, 21; cerebrospinal meningitis, 40; influenza, 19; puerperal fever, 15; cancer, 90, and violence, 137. The cities show a death rate of 15.1 per 1,000 and the country a rate of 9.9. The death rate for Indianapolis was 15.6; Evansville, 15.1; Fort Wayne, 14.8; South Bend, 19.6; Terre Haute, 22.4, and Muncie, 10.7. Of the pneumonia deaths, numbering 347, 176 were males and 171 females. In the corresponding month last year there were 351 pneumonia deaths. Of the 137 deaths by violence, 5 were murders, 20 were suicides and 118 accidental. All of the murders were males, 4 being by gunshots and 1 not named. Of the suicides 13 were males and 7 females. Three males chose carbolic acid, 4 opium or morphin, 1 shooting, 2 hanging. Of the female suicides 4 chose carbolic acid, 2 cutting throat, 1 not named. Of the accidental deaths railroad injuries caused 24; street cars, 2; burns and scalds, 24; crushing injuries, 18; gunshot wounds, 12; falls, 8, and drowning, 3.

Epidemic in Asylum.—An epidemic of scarlet fever has broken out in St. Christopher's Home at Dobbs Ferry. The trustees and physicians are of the opinion that the epidemic was due to germs lurking in the cast-off clothing sent to the institution. There are 12 cases at present. One hundred and eighty children are in the institution.

Gift to Tuberculosis Sanatorium.—The sum of \$23,000 is required to meet bonds of the Stony Wold Sanatorium which mature on March 1, and J. Pierpont Morgan has promised that if the board of directors will raise this sum he will add \$10,000. Two other gifts of \$10,000 have also been reported, one by Mrs. Edward Harkness for the endowment of a bed and the other from a friend who prefers to remain anonymous. There were many other gifts of smaller proportions.

Hospital for Crippled Children.—The fifth annual report of the New York State Hospital for the Care of Crippled and Deformed Children, which removed from Tarrytown to Haverstraw on April 1, 1905, announces the institution in a flourishing condition. An appropriation of \$50,000 which became available in the spring of 1905, made alterations in the buildings possible, and the number of beds was increased from 35 to 45. The report states that it is remarkable how rapidly patients suffering from tuberculous diseases of the joints improve under modern treatment in the fresh air of Rockland County. A friend of the hospital has contributed \$500 for the transportation of eligible indigent patients living in rural districts. Fifty-six patients were treated last year, and 44 patients live in the hospital.

Albany News.—A bill has been introduced into the assembly requiring the labeling of all patent medicines and poisonous articles. It provides a penalty of from \$10 to \$100 for any druggist who sells poisonous articles and materials not so labeled.—New York City wants authority to spend \$250,000 for the purpose of establishing a seashore colony. The colony is intended for the reception of sick and convalescent patients in the city hospitals. It is to be in charge of the Health Department, the president of Bellevue and the Allied Hospitals, and the commissioner of charities, which shall constitute a board of supervision. Provision for the maintenance of the colony is made in the budget and \$250,000 is appropriated for the coming year. No insane person shall be received in the colony.—The state comptroller has paid over to Isaac V. Baker the \$40,000 which the state agreed to pay for his farm as the site of a new state hospital. The matter of payment has been pending on account of the criticism which the selection of this property as the site for a hospital created.—A bill has been introduced into the legislature imposing a tax of \$2 a year on dogs and transferring the dog licensing power from the Society for the Prevention of Cruelty to Animals to the Health Department. Should the bill become a law the society will lose its chief source of income, amounting last year to \$65,000. It is claimed that the society has been mismanaged and is of little use and, again, that the receiving of licenses by any private institution is unconstitutional.

Centennial Meeting.—The centennial meeting of the Medical Society of the State of New York was held in Albany, January 30 and 31, and February 1. For the first time in many years the medical profession of the state met as a united body. Dr. Joseph D. Bryant, New York City, presided, and Hon. Grover Cleveland made the opening address, in which he discussed from the viewpoint of the layman the relations between the physician and his patient. The reorganized society elected the following officers: President, Dr. Joseph D. Bryant, New York City; vice-presidents, Dr. Herman R. Ainsworth, Addison; Dr. Frederick C. Curtis, Albany, and Dr. Jones, Buffalo; secretary, Dr. Wisner R. Townsend, New York City; treasurer, Dr. Alexander Lambert, New York; delegates to the American Medical Association, for two years, Drs. Everard D. Ferguson, Troy; Wisner R. Townsend, New York City; E. Eliot Harris, New York City; Joseph W. Grosvenor, Buffalo; Abraham Jacobi, New York City; Albert Vander Veer, Albany; delegates for one year, Drs. Henry L. Elsner, Syracuse; George R. Fowler, Brooklyn; Hamilton D. Wey, Elmira; William S. Ely, Rochester; Floyd M. Crandall, New York City, and Roswell Park, Buffalo; and editor of the state journal, Dr. James P. Warhase, Brooklyn. The house of delegates of the old state society was continued for another year.

Buffalo.

City Bacteriologist's Salary Raised.—The Board of Health of Buffalo has decided to raise the salary of the city bacteriologist from \$1,500 to \$1,800 a year and the salary of the assistant bacteriologist from \$1,200 to \$1,500.

Fair and Ball for German Hospital.—The fair for the benefit of the German Hospital netted between \$25,000 and \$30,000 for the hospital. A charity ball for the benefit of the German Hospital will be held at City Convention Hall, February 20.

Fine for Negligence Revoked.—The fine of \$10 and costs entered by the Health Department of Buffalo against Dr. F. M. Rich has been revoked by the board of aldermen, it having been proven conclusively that Dr. Rich was in no way negligent in not reporting a case of contagious disease.

Physicians Endorse University Extension.—The physicians of Buffalo held a meeting January 19 at the University Club for the purpose of giving an impetus to the university extension movement in creating a college of liberal arts in addition to the professional schools now existing. The physicians responded loyally to the call for subscriptions, and \$20,000 was subscribed for this purpose, with the possibility of raising double that amount. It is especially gratifying that the medical profession should have been among the first to respond so liberally for such a high purpose, and no doubt the example set by the medical profession will influence the legal, dental and other professions to contribute their quota for the endowment and maintenance of a school of liberal arts.

New York City.

New York Academy of Medicine.—The section on obstetrics elected the following officers: Chairman, Dr. Arnold Sturm-dorf; secretary, Dr. Howard C. Taylor.

Estate for Hospital Society.—The German Hospital Society of Brooklyn, by an interlocutory decision handed down by the Supreme Court, receives the greater part of the estate of the late Mrs. Edward N. Rosenbaum, which is estimated at \$75,000.

Lee to Lecture on Fatigue.—The seventh lecture in the Harvey Society course will be delivered by Prof. Frederick S. Lee of Columbia University at the New York Academy of Medicine on Saturday, February 3, at 8:30 p. m. Subject, "Fatigue."

Appendicitis.—Dr. Andrew J. McCosh was operated on for appendicitis January 26. The appendix was removed and two days later the patient was reported as doing well and in no danger.—Dr. George R. Fowler, Brooklyn, has been operated on for appendicitis. He is very ill, but is doing well.

For Clean Street Cars.—Borough President Coker will appoint a committee of 100 whose aim will be to compel the Brooklyn Rapid Transit Company to give better service and to keep its cars clean and warm. All the boards of trade will join with the committee to aid in carrying out the crusade.

Fire in Private Hospital.—A fire occurred in the private sanatorium conducted by Miss Anna L. Alston on the morning of January 25. By the unusual coolness and quick work of the nurses a number of surgical patients were carried from the top floor to the main floor in a very short time. The loss to the hospital was about \$3,000.

Plan to House Municipal Departments.—Comptroller Metz will submit a proposition to the board of estimate for the erection of a municipal building on a site opposite Cooper Square belonging to the city, which will house the health, tenement-house buildings and corrections departments. The present scattered locations of these related departments is a great inconvenience.

To Help Sick Children.—The Speedway Country Homes Society, whose work is the placing of sick children from the tenements in private country homes, held its annual meeting on January 25. It is intended to build some homes for tuberculous children, and for this purpose Mrs. Andrew Carnegie has promised \$10,000 and Miss Helen Gould announces that she will build one such home.

Contagious Diseases.—There were reported to the sanitary bureau for the week ending January 20, 1,487 cases of measles, with 17 deaths; 448 cases of tuberculosis, with 159 deaths; 359 cases of diphtheria and croup, with 46 deaths; 237 cases of scarlet fever, with 10 deaths; 35 cases of typhoid fever, with 5 deaths; 28 cases of cerebrospinal meningitis, with 15 deaths; and 205 cases of variola. A total of 2,799 cases and 252 deaths.

Personal.—Dr. Henry Dwight Chapin has been appointed medical director of the Speedway Country Homes Society. Dr. Thomas R. Maxfield of Brooklyn has been appointed acting assistant sanitary superintendent of the department in Brooklyn by the Board of Health in place of Dr. T. Lewis Fogarty, who was removed by the board.—Dr. J. P. Murray of Brooklyn was appointed medical examiner to the finance department at a salary of \$2,500.

Hot Winter Healthful.—It was announced at the Board of Health that the warm weather had materially reduced the death rate in this city. There were 45 less deaths for the week ended January 20 than for the corresponding week of last year. All pulmonary diseases showed a noticeable decrease. During the week ended January 27 there was an increase in the number of deaths from influenza, and the fear is expressed that this affection is becoming epidemic.

New West Side Clinic.—A clinic exclusively for women and children will soon be opened somewhere on the West Side under the supervision of Mrs. Harry Wallerstein, a graduate of the New York Medical College and Hospital for Women. Its work as proposed will be largely preventative, as those will be cared for who are not sick enough to go to a hospital. When necessary, physicians from the clinic will visit patients in their homes. There is at present \$1,500 in the treasury.

OHIO.

Medical Club Election.—The Canton Medical Club has elected the following officers: President, Dr. Harry M. Schuffell; vice-president, Dr. Lauren E. Flickinger; recording secretary, Dr. Clara E. Fraumfelter, and censors, Drs. Frank E. Hart, George A. Kelley and J. Frank Kabler.

Alumni Election.—The annual election of officers of the Cincinnati Chapter of the Ohio Medical College Alumni was held at the residence of Dr. John Ranley, Cincinnati, January 17. The following were chosen: President, Dr. William Gillespie; vice-president, Dr. Earl Harlan; secretary, Dr. Charles Langsdale, and treasurer, Dr. B. M. Weekley.

Personal.—Dr. James C. Reinhart has been appointed health officer of Toledo, Ohio, vice Dr. Walter W. Brand.—Dr. George Dock, Ann Arbor, Mich., has been made honorary member of the Academy of Medicine of Toledo and Lucas County, Ohio.—Dr. Otto Geier, of the medical staff of Christ's Hospital, Cincinnati, was operated on at that institution January 21, for appendicitis.

Stark County Medical Society.—At the annual meeting of this society the following officers were elected: Dr. Alonzo B. Walker, Canton, president; Dr. Frank W. Gavin, Canton, corresponding secretary; Dr. George F. Zininger, Canton, treasurer, and Drs. Harry P. Pomeroy, Canton; Jacob F. Marchand, Canton; William C. Steele, New Berlin; Leon B. Santee, Marlboro; Neal W. Culbertson, Massillon, and Daniel W. Gans, Massillon, executive committee.

PENNSYLVANIA.

Bequest.—By the will of Mrs. Annie Hartmyer, St. Joseph's Hospital, Lancaster, receives \$500.

Consumption Hospital in Pittsburg.—A sanitarium for the treatment of pulmonary tuberculosis is to be established in Pittsburg, at the former residence of William McConway, on Herron Hill, under the name of the Pittsburg Sanitarium. Mr. McConway has agreed to give the free use of his former residence and ground for a stated period, and if the hospital proves a success it is understood that he will deed it over to the corporation.

Pennsylvania's Relief Report.—The monthly report of the Employers' Relief Fund for the Pennsylvania Railroad Company's lines east of Pittsburg and Erie, shows that the payments of benefits to its members and families of deceased members for December amounted to \$134,038.30, of which \$52,882.20 was on account of death and \$81,156.10 on account of disability by sickness and accident. The payments thus far are stated to have amounted in the aggregate to \$14,335,680.87, of which \$5,891,377.34 was on account of death claims and \$8,444,303.53 on account of disability.

Medical Officers Sustain Dr. Dixon.—At a meeting of the Clinton County Medical Society, held in Lock Haven, January 21, the following resolution was unanimously adopted:

WHEREAS, There has been some opposition in Lock Haven and throughout Clinton County to the efforts of Dr. Samuel G. Dixon, commissioner of health of Pennsylvania, to enforce the vaccination laws of 1885, the members of the Clinton County Medical Society declare to place themselves on record as upholding Dr. Dixon in his efforts to enforce the vaccination laws of Pennsylvania. We unanimously agree that the only way to prevent smallpox is by vaccination, and those who try to prevent and bring it into contempt only show their ignorance and have never been treated or had anything to do with smallpox, otherwise they would not try to defeat the only prevention of this noxious disease.

Medical Officers Elected.—At the annual meeting of the Beaver County Medical Society, January 11, the following officers were elected: President, Dr. James F. Elder, New Brighton; vice-presidents, Drs. W. Winfield Simpson, New Brighton, and George Y. Goul, Baden; secretary, Dr. James K. White,

New Brighton, and treasurer, Dr. H. M. Shallenberger, Rochester.—At the annual meeting of the Delaware County Medical Society, January 4, the following officers were elected for the year: President, Dr. M. P. Dickeson, Media; vice-president, Dr. Jonathan L. Forwood, Chester; treasurer, Dr. D. W. Jeffries, and secretary, Dr. Linnaeus S. Fussell, Media.—At the annual meeting of the Elk County Medical Society, January 12, the following officers were elected: President, Dr. Elmer E. Livingston, Johnsburg; vice-presidents, Drs. Joseph G. Flynn, Ridgway, and P. W. Leitsell, Portland Mills; secretary, Dr. M. M. Rankin, Ridgway, and treasurer, Dr. Alfred Mulhaupt, St. Marys.—At the annual meeting of the Montgomery County Medical Society, January 10, the following officers were elected: President, Dr. Elmer G. Kriebel, Worcester; vice-presidents, Drs. J. Q. Thomas and J. Howard Seiple, Center Square; recording secretary, Dr. Harry H. Whitcomb, Center Square; corresponding secretary, Dr. Joseph K. Weaver, Norristown, and treasurer, Dr. S. Nelson Wiley, Norristown.—At the election of the Pittsburg Academy of Medicine Dr. Edward H. Small was elected president; Dr. Glendon E. Curry, vice-president, and Dr. Thomas G. Simonton, member of the committee on scientific program.

Philadelphia.

Disease Closes Schools.—At the direction of the officers of the Bureau of Health the Cambria public school was closed for disinfection January 25, seven of the pupils being ill with diphtheria; three schools were also closed by the Board of Health in West Philadelphia on account of an epidemic of measles among the children of that section.

Personal.—Dr. and Mrs. George F. Baker sailed for Europe January 20.—Dr. Bernard Berens was elected president of the Athletic Club of Philadelphia, January 23.—Dr. S. Weir Mitchell read his poem: "Francis Drake, a Tragedy of the Sea," before the Pennsylvania Fellowship of Fine Arts, in the Academy of Fine Arts, January 22.—Dr. A. Victoria S. Haensler and Dr. and Mrs. L. Webster Fox sailed for Port Antonio, Jamaica, January 25.—Dr. Charles K. Mills has been appointed consulting physician to the Orthopedic Hospital and Infirmary for Nervous Diseases.

Bequests.—The executors and trustees of the Simon Muhr estate have made additional distribution of \$9,000, \$1,500 of which goes to the Jewish Hospital Association, \$300 to the Pennsylvania Hospital, \$300 to the Jefferson Medical College, \$300 to the Philadelphia Home for Incurables, \$150 to the Philadelphia Polyclinic Hospital, \$150 to the Philadelphia Lying-in Hospital, \$120 to the Women's Hospital of Philadelphia, \$120 to the Children's Hospital, and \$120 to the West Philadelphia Hospital for Women.—In adjudicating the estate of Harriet Richards the Orphans' Court awarded a bequest of \$10,000 to establish free beds in one or more hospitals.

The Cost of Tuberculosis to the State.—At the tuberculosis exhibition, January 24, Dr. Leonard Pearson, state veterinarian, in discussing state control of tuberculosis, said that deaths and illness from tuberculosis in Pennsylvania is responsible for a loss of \$24,000,000 each year. Estimating that the average citizen is worth to the state at least \$1,000, and that there are 12,000 deaths annually from the white plague, Dr. Pearson says the loss, therefore, from this would be \$12,000,000. In addition to this loss of earning power during the two or three years' illness and the increased cost or maintenance during this period is probably equal to the direct loss from death, making the total loss to the state \$24,000,000. He said that there are at all times 25,000 to 30,000 persons who are ill from tuberculosis in Pennsylvania. The state should provide sanatoria for consumptives, not merely for their own benefit, but for the protection of uninfected citizens. The importance of this is shown by the fact that three or four people contract the disease from every person who dies of it.

Portrait of John Morgan for University.—A large oil painting of John Morgan, founder of the medical school of the University of Pennsylvania, has just been added to the large collection of portraits owned by the university and will occupy a position on the walls of Hoston Hall. The portrait is the gift of the Hon. David T. Watson, Pittsburg, who is a descendant of John Morgan, the founder of the medical department of the university, the first medical school in America. The tablet fastened to the frame is inscribed as follows: "Dr. John Morgan, born 1735, died 1789. Copy of original by Angelica Kaufman, in Rome, 1763-64." Dr. Morgan was born in Philadelphia in 1735, and was graduated in 1757 with the first class of the College of Philadelphia, which later became the University of Pennsylvania. He subsequently studied medicine in Philadelphia, later in Edinburgh, Paris and Padua, obtaining

his professional degree from Edinburgh in 1763. He became the first teacher of medicine in the College of Philadelphia, and with William Shippen organized the medical school of the University of Pennsylvania. He was one of the early members of the American Philosophical Society, and also the first general director of the medical service of the Continental Army.

Health Report.—The total number of deaths reported for the week was 583. This is a decrease of 50 from the number reported last week, and an increase of 4 over the number reported in the corresponding week of last year. The principal causes of death were: Typhoid fever, 17; measles, 15; whooping cough, 4; diphtheria, 12; meningitis, 4; tuberculosis, 70; cancer, 21; apoplexy, 27; heart disease, 49; acute respiratory disease, 121; enteritis, 33; Bright's disease, 45; premature birth, 9; old age, 14; suicide, 3; accidents, 29, and marasmus, 6. There were 476 cases of contagious disease reported, with 29 deaths, as compared with 373 cases and 37 deaths for the previous week. In view of the epidemic of measles the health authorities have decided to place yellow placards on houses in which there is a patient suffering from this malady. By this means the public will be warned and it is hoped the prevalence of the disease will be diminished. There were 718 cases of measles reported last week. The yellow placard will also be placed on houses in which there are patients suffering from chickenpox. Sixty-three cases of this disease were reported for the week as compared with 65 reported for the previous week.

VIRGINIA.

Typhoid fever of a very malignant type has become epidemic in certain parts of Frederick County.

Bequest.—The late Emanuel Millhiser left by his will \$1,000 to the Sheltering Arms Hospital of Richmond.

Personal.—Dr. Aaron Jeffery is recovering after a severe fracture of the leg, caused by being thrown from his carriage. —Dr. D. D. Wilcox, Petersburg, while horseback riding, was thrown from his horse and had his leg broken.

Election.—At the annual meeting of the Newport News Medical Society the following officers were elected: Dr. Richard T. Styll, president; Dr. Thomas J. Sims, vice-president, and Dr. Anna M. Randolph, secretary and treasurer.

Must Not Do Contract Work.—The Petersburg Medical Faculty has decided that a member of that body can not, without violating the rules of the faculty, make an agreement with a secret fraternal order to give medical attendance to its members at contract prices.

Smallpox.—For several weeks past the citizens of South Hill and vicinity have been in much doubt whether a prevailing disease was chickenpox or smallpox. An expert from the State Board of Health has just visited the town and diagnoses the trouble as a mild form of smallpox. Quarantine and sanitary measures will be instituted at once.

GENERAL.

Typhoid Fever in Mexico.—An epidemic of typhoid fever in the City of Mexico has assumed such proportions that a meeting of the principal physicians, attended by President Diaz and Governor Escandon, has been held to discuss energetic means of stamping it out.

Isthmus Health Excellent.—The sanitary report for the Canal Zone for the month of December shows that the health conditions remain excellent. During the month there was only one case of yellow fever, that of an employé of the commission who was taken sick at Colon, December 11. In the city of Panama the last case occurred November 11. At present there is on hand no quarantinable disease of any kind. The sick rate of the employés continues very low. With a force of about 22,000 there were on the average during the month 427 in the hospital. This would give a sick rate of slightly over 19 a 1,000. While the sick rate is very small, the death rate has been large. This was due to the large number of fatal cases of pneumonia occurring among the negro employés. Of the 74 deaths, 33 were due to pneumonia, and all of these cases of pneumonia occurred among the negroes. Leaving out these 33 cases of pneumonia, the death rate for the month would be at the rate of about 22 a 1,000 a year. The white employés suffer much less than the negroes. Among the whites there were only 4 deaths, and of these only 2 were from disease. This would give an annual death rate among the whites of only 8 each 1,000. The death rate among the negroes, on the other hand, would give an annual death rate of about 44 each 1,000. Colonel Gorges reports that it is difficult for him to account for this great difference. Of course,

the whites, on the average, take very much better sanitary care of themselves, sleep under mosquito bars, take quinin, and observe other sanitary regulations to a much greater extent than do the negroes.

CANADA.

Vital Statistics.—During the last half of 1905 Winnipeg had 1,996 births, 1,064 deaths, and 837 marriages. —Peterborough, Ont., with a population of 14,500, had 224 deaths in 1905, 23 less than in 1904. It is the lowest death rate of any Canadian city. —The total number of deaths in Ontario in December, 1905, was 2,416.

Prevalent Diseases.—In Ontario, during December, 1905, 1,289 cases of smallpox were reported from 20 municipalities; 172 deaths were reported from consumption, and there were 152 cases of typhoid fever, with 45 deaths. —There is an epidemic of smallpox in the village of St. Cyrille, near Drummondville, P. Q., no less than 150 cases having been reported.

Personal.—Dr. G. A. Charlton, Regina, has been appointed bacteriologist of the department of agriculture, for the province of Saskatchewan. —Dr. George R. McDonagh, Toronto, has gone to Southern California for two months. —Dr. C. M. Murray, Toronto, has gone to Europe. —Dr. S. H. Westman, Toronto, is in that city for a month, before he returns to England for further postgraduate work. He has spent the last two years in London. —Dr. Colin Campbell, late house surgeon at Moorfields, London, Eng., has returned to Toronto, and will probably establish himself as an oculist in that city. —Dr. G. W. Badgerow, Toronto, who for six years has been doing postgraduate work in London, after a brief visit to Toronto, has returned to England. —Dr. R. R. Hopkins has been appointed medical health officer of Toronto Junction, Ont., vice Dr. H. Mason, resigned.

Hospital and College News.—Galt, Ont., will establish a cottage hospital for incurable consumptives, the first of its kind in Canada, and will appeal to the Ontario government for financial aid. —The new Manitoba Medical College was formally opened January 26. —The woman's auxiliary in connection with the Winnipeg General Hospital, in 1905 collected over \$3,700 for that institution. —The Toronto General Hospital fund continues to grow and now amounts to \$1,101,946.

—Dr. John Noble, Toronto, has been elected chairman of the Toronto Board of Health, and has revived the question of Toronto building a consumption hospital, which he strongly favors. Dr. Sheard, the medical health officer, who is at present in New York, as the guest of the Canadian Club of that city, thinks there should be no undue haste in the erection of such a building, as the present hospitals of Toronto are doing very well in the matter of caring for this class of the sick.

Canada's Public Health Report.—Dr. Montizambert, director-general of public health for Canada, has his annual report for 1905 ready for presentation to parliament at the meeting of that body in the immediate future. He states that owing to the fact that there is no smallpox in those states bordering on Canada, port officers and inspectors have been withdrawn. During 1905 careful inspection has been carried on both on the Atlantic and Pacific, special inspection of vessels from San Francisco having been discontinued on Jan. 1, 1906. Dr. Montizambert again emphasizes the important need of a dominion department of public health under a responsible minister of the crown, so that all matters affecting the health of the dominion might be consolidated under one head. The leper lazaretto at Traenadie, N. B., is also referred to in his report. There are now on the books of that institution 17 patients, 10 males and 7 females. There were no deaths during the year. Two new patients were admitted during 1905. It is said that good results continue to follow the treatment by Chaulmoogra oil and strychnia, with external applications of creolin. One patient was discharged cured, but ordered to report for inspection from time to time.

Half Rates to British Medical.—Arrangements are announced for the British Medical Association meeting in Toronto, Ont., Aug. 21-25, 1906, whereby local travel in Canada will be on the certificate plan, allowing free return, regardless of number in attendance. Passengers going by rail and returning by R. & O. Navigation Company, or vice versa, rate to be one and one-half fare. Travellers from Europe who present certificates signed by the secretary of Eastern Canada Passenger Association, and countersigned by the secretary of the Canadian committee, or the secretary of the British Medical Association, will be granted one-half lowest one-way first-class rail fare; round-trip tickets at lowest one-way first-class rail fare; between all points in Canada. Rates to Pacific coast subject to concurrence of Trans-Canadian Passenger Association. Dates

of sale, July 1 to September 30, inclusive. Final return limit September 30. Side trip tickets to be sold from Toronto to delegates from the Maritime Provinces, from all points west of Port Arthur and from the United States, on presentation of validated certificate or deposit receipt at lowest one-way first-class fare for the round trip to all points in Canada. Dates of sale, August 23 to September 1, inclusive. Return limit September 30.

FOREIGN.

A New Hospital at Maan, Turkey.—At Maan, on the great oriental railway of Hedjaz, a new hospital of 70 beds was opened January 2, in the presence of the chief of the sacred caravan and numerous pilgrims.

International Congress of Medical Electricity.—The third International Congress of Medical Electricity and Radiology will be held at Milan September 5 to 9. Information as to membership may be obtained from Dr. Herschell, 36 Harley Street, London, W.

Plague of Locusts at Kimberley, South Africa.—During the early part of December the inhabitants of Kimberley suffered from an invasion of locusts. The *British Medical Journal*, January 20, has an illustration showing the wall of the Kimberley Hospital almost covered by the insects.

Damages for Infection of Wet Nurse by Syphilitic Infant.—The court at La Rochelle, France, has awarded about \$2,400 for damages claimed by a wet nurse for infection with syphilis from a syphilitic infant. The defendant in the case is the Assistance Publique, that department of the administration which has charge of all the public hospitals, orphan asylums, etc., throughout the country.

Society for the Protection of Children in Turkey.—The Constantinople correspondent of the *Lancet* states that a society exists in that city for the protection of children. It is under the patronage of the Spanish minister, the Marquis Camagor, and many well-known members of the upper classes of the city. The society is for the purpose of protecting infants, foundlings, and small children generally. This society possesses a hospital where little ones of every race and denomination receive the best care and treatment that can be provided for them in the city.

International Hygiene Exhibition.—An exhibition will be held at Milan, Italy, from April to November, 1906, on the occasion of the opening of the Simplicon tunnel. It will include a section of hygiene embracing general hygiene, public health, sanitary services, rural and industrial hygiene. Another part will comprise all that relates to the etiology, diffusion and prophylaxis of tuberculosis, and to institutions for its treatment. A meeting of the Italian National Antituberculosis Congress will be held at the same time. The president of the sanitary commission is Prof. Luigi Maciagnalli, while Dr. Francesco Gatti will preside over the antituberculosis congress.

Sunday Rest for Drug Stores.—The National Board of Public Health of the Republic of Argentina has issued some new regulations respecting Sunday rest. Among them is one which requires the pharmacies to close on Sunday, one in each precinct remaining open, while the others are closed. Each pharmacy takes its turn in remaining open and the board has issued a list of the various pharmacies with the date of their open Sunday, the police being instructed to enforce the decree. In Germany the physicians in a number of towns are combining in the same way to obtain their Sunday rest. They have been in the habit of holding office hours on Sunday as on other days. Now only one office will be open in a precinct, each physician taking his turn.

Medical College at Lucknow, India.—A medical college for the United Provinces is to be established at Lucknow in commemoration of the visit of the prince and princess of Wales. A branch college for women is proposed, and this will probably be named after the princess of Wales. It will be completely separate from the college for men, and there is ample space whereon to build it close to the Lady Dufferin Hospital. The Indian correspondent of the *Lancet* states that in this part of India there is no college for the higher medical training of women. There are only classes for female hospital assistants. It is hoped to get educated Hindoo women to take up medicine. It is announced that the education in this college will be conducted with every regard for the customs of the country.

Suits Against Unqualified Practitioners in Germany.—A quack named Baumann was recently sentenced to four months' imprisonment in Berlin for advertising a universal specific which was said to have done harm in many instances. On his appeal to a higher court the sentence was reduced to a

fine of \$125, the court accepting as a mitigating circumstance that Baumann was firmly convinced of the healing virtues of his vaunted specific. In another suit brought against a "nature healer" named Mistelsky, a fine of \$250 had been imposed, but during the delays of his appeal to a higher court, the case passed beyond the legal limit of one year, and consequently the upper court had to dismiss the suit. Mistelsky was allowed to go without penalty, and he published abroad this occurrence as his "triumphant vindication by the courts against the malicious persecution of the local medical chamber" which had brought the suit.

Restriction of X-Ray Work to Qualified Practitioners.—A committee was recently appointed by the Paris Académie de Médecine to report on the question whether the medical use of the Roentgen rays should be restricted. The committee was composed of Brouardel, Debove, Gariel, Guéniot, Harriot, Motet, Pouchet and Chauffard. They emphatically advocated that the medical application of the Roentgen rays should be legally restricted to duly qualified persons. Their conclusions are based on the established facts that the medical use of the Roentgen rays may lead to serious accidents, and that certain practices may prove a social danger, while, on the other hand, only qualified physicians or health officers or regularly licensed dentists (in the domain of odontology) are capable of interpreting the results obtained from the point of view of the diagnosis and treatment of affections. The discussion on the subject was published in the *Bulletin of the academy*, Nos. 2 and 3.

Medical Sociology in Germany.—The Berlin medical faculty has recently arranged for a course of lectures on medical sociology, to be delivered by Professor Kirschner, as part of the regular medical curriculum. He is also to deliver a course of postgraduate lectures this summer on the new regulations in regard to communicable diseases. A society was organized a year ago, with headquarters in Berlin, entitled the Society for Medical Sociology, Hygiene and Medical Statistics (*Ges. f. soziale Medizin, Hyg. und Medizinalstatistik*). R. Lennhoff was the prime mover in its organization and the journal of which he is editor, the *Medizinische Reform*, has been made the official organ of the association, and is now appearing under the name, *Wochenschrift f. soziale Med., Hyg. u. Med. statistik*. A yearbook on sociologic hygiene and demography has been published during the last five years by A. Grotjahn and F. Krieger, and they have now founded a periodical to contain original works on medical sociology, medical statistics, workmen's insurance, sociologic hygiene and the borderland problems of medicine and social economics. The yearbook is published by Gustav Fischer, Jena, but the journal is to be issued by F. C. W. Vogel, Leipzig. There is still another periodical devoted to these topics published in Germany, the *Archiv f. soziale Medizin und Hygiene*, now in its second year. It is edited by M. Fürst and K. Jaffe, both of Hamburg.

Plague in Japan.—According to *Public Health Reports*, plague has made its appearance at Shimonoseki, where three probable cases have been discovered. Shimonoseki is separated only by a narrow strait from Moji, one of the most important coaling ports in the East, where many vessels bound for America call. There being no American consul at Moji, United States consular bills of health can not be obtained. Consul Sharp reports from Kobe that the locality in which a plague case has been found is inclosed by a zinc fence, and after all the rats on the premises have been destroyed, the place is carefully disinfected. Persons suspected of being infected with the disease are removed for a certain period to a place of detention, where their physical condition is carefully watched. They are allowed to return home after it has been satisfactorily proved that they are not infected with the disease. To encourage the extermination of rats a reward is given by the authorities for each living or dead rat produced in Kobe and Osaka, and in the villages of these districts. These rats are examined, and when plague bacilli are discovered in any of them the places in which they were caught are disinfected in the same manner as when plague patients are found. Postmortem examinations are held on all deceased persons and daily examinations of the health of the public are made by the medical inspectors. Compulsory house cleaning and disinfection are now being enforced in the districts where it is thought the disease may be lurking.

Mexican National Medical Congress.—The national medical association of Mexico, known as *Pedro Escobedo*, held a successful medical congress in the city of Mexico, January 9 to 12. The congress was opened by the president of the republic, who was presented with a gold medal bearing on one side the words: "Asamblea de la Sociedad Pedro Escobedo," with the

date, and on the reverse: "Jubileo Profesional del señor Dr. Don Eduardo Liceaga." A similar gold medal was presented to Liceaga, and duplicates in silver were given to all the delegates to the congress. The opening meeting was a brilliant gathering, with music and recitations, including a poem written for the occasion. The president of the society, Dr. G. Mendizabal, gave a historical sketch of medicine in Mexico and of the society, and then introduced the honorary president, Dr. E. Liceaga, chief of the Superior Council of Health, as the orator of the evening. His address was on "Yellow Fever," and he reported the great strides made in eradicating this disease in Mexico, and outlined the work being done by his department. He announced that notwithstanding that the disease is imported from time to time, it is kept under constant control. At the date of speaking there was only a single yellow fever patient in the republic, and he was well on the road to recovery. He further distributed a number of circulars among them, one addressed to physicians, one to plantation owners and one to railroad officials, all dealing with the prophylaxis of yellow fever, written in simple, popular language. Among the subjects appointed for discussion at the regular meetings of the congress were: "Early Diagnosis of Tuberculosis," "Fever," and "Bases for Treatment of Epilepsy." So many communications were presented that a supplementary meeting was found necessary. Great interest was aroused by a report of J. D. Morales on the scientific production of the national beverage, pulque. He showed that sterilization of the raw material did not interfere with the quality of the drink, while it eliminated the disagreeable odor and the necessity for the use of poisonous substances in its preparation. Pruneda's article on "False Incipient Tuberculosis," and Guzman's on "Rachialgia as an Early Sign of Tuberculosis," attracted much attention. The section on hygiene adopted resolutions to the effect that public drunkenness should be declared a misdemeanor, that a training school for nurses and a Pasteur institute should be established in every state, and that arrangements should be made for country schools for weakly and scrofulous children to teach them gardening, farming, etc. The daily papers of the city of Mexico gave very full reports of the congress, especially of the ovation to Liceaga. He has made many friends in the United States during his attendance at various scientific congresses, etc.

Proposed Reforms for International Medical Congresses.—The German national committee in charge of arrangements for the approaching International Medical Congress, to be held at Lisbon in April, will present the following two proposals at the Lisbon congress and urge their adoption: "1. The organization of an international bureau for the general medical congresses, which will act during the intervals between the congresses. The members of the bureau to be the presidents of the past and approaching congresses and the members of all the national committees. This central office should have its headquarters in Paris, and its task will be to preserve continuity and order in the arrangements of the congresses, especially in the making out of the programs, regulating the sections, appointing topics for discussion and selecting speakers to present the various themes, and the honorary presidents, working always in co-operation with the committee of organization of the congress. Motive: The need for some international body to serve as a court of appeal in matters affecting these international congresses has long made itself felt, to prevent or smooth away differences that may arise between the committee of organization and the representatives of the special sciences. At the same time, such an international body would serve by regulating the relations between the great general congresses and the international specialist congresses, and also with the medical congresses in the different countries. 2. The general international medical congresses should be held not oftener than once in five years. Motive: It is generally acknowledged that the international congresses have lost in prestige of late years. This is due principally to the brief interval between them. In case they occurred only once in five years the preparations for them would probably be more carefully made, and more energy would be devoted to the solving of scientific problems, these forces now being drained away by their being called on so constantly for scientific gatherings of such kinds. Besides this, if the international congresses were not held so frequently, it would be easier to find suitable places at which to hold them." Valdeyer and Posner are chiefly responsible for the drafting of these resolutions. They are to be submitted to the various national committees for discussion in the hope that something tangible will result in the way of the desired reforms. The original text of the resolutions is given in the *Berliner Klin. Wochft.*, January 15, of which Ewald and Posner are the editors.

Pharmacology

The Relation Between Physician and Pharmacist.

There is a mutual dependence of pharmacy and medicine on one another: The doctor needs the pharmacist and the pharmacist can't get along very well without the physician. There is no antagonism between the honest pharmacist and the honest physician. On the contrary, there are few physicians who do not have especially close relation with some druggists with whom they frequently consult on pharmaceutical matters. In the propaganda for honest pharmacy as against secrecy and fraud in drugmaking the pharmacist is very much interested—certainly as much so as is the physician. Consequently the drug journals have had much to say about the Council on Pharmacy and Chemistry and its work. Some of these journals have jumped to the conclusion that there would be more money for them in siding with the nostrum makers, but the better journals, those which are recognized as representing scientific pharmacy—and these, we are glad to say, are in the majority—have seen in this movement a promise of better things, and a return to legitimate pharmacy, and have heartily endorsed the movement. Among the latter is the *Druggist's Circular*, of New York, a journal that for nearly fifty years has been recognized as representing the best interests of pharmacy. For years it has been fighting against the growing tendency toward the commercializing of the drug store, which has made pharmacy a mere incident to the business, and the compounding of prescriptions a side issue—the nostrum prescribing doctor being mostly to blame for the latter condition. In the past the *Druggist's Circular* has exposed more fraudulent nostrums than any other drug journal, and it is still courageously carrying on the work. It has now to fight a \$50,000 libel suit brought against it by a German chemical company because it dared to publish what it believed to be the truth. This leads us to suggest that the average physician will find in a good pharmaceutical journal—not a trade drug journal—many hints and suggestions about drugs and prescribing that will be most valuable to him. Not only this, but if he were reading such a journal he would be able to see himself as he is seen by the man behind the prescription case, which sometimes would be advantageous to both. He would see himself severely criticised occasionally—often justly so—and this would be a good thing.

For the Safety of Yourself and Your Child.

Under the above heading the *Ladies' Home Journal* for February prints a proposed bill, with a preface thereto, both of which we quote, as follows:

We give below a carefully prepared bill which should be introduced into the legislature of every state this winter. Ask the member of the legislature from your district to do this. Then when the bill is introduced it should be the duty of every man and woman to use his or her influence to see to it that the bill is passed and becomes a law. You can do this by asking or writing your representative and insisting that he shall vote for it. The entire combined influence of the manufacturers of the "patent medicines," and of the newspapers which derive profit from their advertising, will be used with your representative against such a measure. But if the people say "This bill must pass" it *will* pass, and this is what you, as one of the people, can do.

NOW WILL YOU DO IT?

THE TIME HAS COME FOR YOU TO ACT.

AN ACT

TO REGULATE THE MANUFACTURE AND SALE OF "PATENT" AND "PROPRIETARY" MEDICINES.

BE IT ENACTED by the Legislature of the State of.....

SECTION I. Each package, bottle, box or other parcel containing what is commonly known as a "patent" or "proprietary" medicine of any kind or in any form, intended for internal consumption by human beings, other than a medicine specially compounded on the written order or prescription of a physician duly authorized to practice his profession in this state, which shall be hereafter manufactured within this state, or which shall be hereafter manufactured without this state and exposed or offered for sale, or sold or given away, or otherwise disposed of, within this state, shall have both on the outside wrapper of such package, bottle, box or other parcel, and also on the label affixed to such package, bottle, box, or other parcel, in plain English, printed in black letters on white paper, of a size not smaller than of type eight point, so called, a complete schedule showing all the ingredients contained in such "patent" or "proprietary" medicine, and the exact proportions of each ingredient thereof.

SECTION II. Whenever any such "patent" or "proprietary" medicine shall contain more than 8 per cent. of ethyl alcohol, or more than one-twenty-fifth of 1 per cent. of morphin, heroin, cocaine, or of the salts or equivalents or derivatives of the same, or any of them, or more than one-fourth of 1 per cent. of chloral hydrate, or any quantity of belladonna, cotton-root, ergot, or other abortifacient, there shall be printed in plain English, in red letters of a size not smaller than eight point, so called, on white paper, in addition to the schedule of ingredients heretofore required, both on the outside wrapper of the package, bottle, box or other parcel containing the same, and also on the label affixed to such package, bottle, box or parcel, a notice reading as follows:

"This package, or bottle or box or parcel as the case may be, contains (here give the name and proportion or percentage of the drug as the case may be), and is therefore under the Act of the Legislature of the State of marked

"POISON,"

and also the single separate word "poison" which shall be printed separately on a line by itself, in bold-face type, and in letters not less than onesixteenth of an inch.

SECTION III. The Board of Health of this state is hereby empowered, immediately on the passage of this act, and from time to time thereafter, to make, or cause to be made, a chemical analysis of "patent" or "proprietary" medicines, manufactured, or exposed or offered for sale, or sold or given away, or otherwise disposed of, within this state, for internal consumption by human beings, other than those specially compounded on a physician's written prescription as aforesaid. If any such analysis shall show that there has been, with respect to any such "patent" or "proprietary" medicine, a failure to comply with the requirements of this act, said board shall at once notify the district attorney of any county in this state in which the said "patent" or "proprietary" medicine is manufactured, or exposed or offered for sale, or sold or given away, or otherwise disposed of, whose duty it shall be to prosecute the person, firm or corporation so violating the provisions hereof.

SECTION IV. Any chances, either in the ingredients or in the proportions or percentages of the ingredients in any such "patent" or "proprietary" medicine manufactured within this state, shall be at once reported by the manufacturer thereof to the Board of Health of this state.

SECTION 5. Any person, firm or corporation who shall manufacture, or expose or offer for sale, or sell, or give away, or otherwise dispose of, any such "patent" or "proprietary" medicine within this state, in violation of the provisions of this act, or any of them, shall be guilty of a misdemeanor and on conviction thereof shall be punishable therefore by a fine of not less than five dollars (\$5.00) nor more than five hundred dollars (\$500), or imprisonment for not less than thirty (30) days nor more than six (6) months, or both.

SECTION VI. All acts or parts of acts inconsistent herewith are hereby repealed.

SECTION VII. This act shall take effect on the day of 1906.

Thus far we have quoted from the *Ladies' Home Journal*. We take the liberty of making the following suggestions:

The provision limiting the maximum strength of morphin and its derivatives to one twenty-fifth of 1 per cent. would represent a morphin strength equivalent to one grain in 44 fluid drams (0.04 gm. in 100 c.c.). The average teaspoonful is equivalent to 80 minims (5 c.c.) instead of one fluid dram, and it would contain about 1/32 grain of morphin. This is about what many of these medicines now contain; one of the largest used and which has to be labeled "Poison," in England, contains little more morphin than this.

The manufacturers of soothing syrups, cough syrups, "baby's friend," etc., could easily reduce the morphin amount to place their medicines beyond the law, with an increased consumption and sale as the only result. The quantity allowable should be reduced at least one-half—or, in other words, to one-fiftieth of 1 per cent.—but preferably no medicine containing opium, morphin, cocaine or their salts or derivatives in any proportion should be exempt; the "Poison" label should be used always when any of these drugs are contained in the preparation.

It is feared that the requirement that all medicines containing 8 per cent. alcohol should be labeled "Poison" is too dra-

tic, since all the tinctures of the United States Pharmacopeia, spirits or essences, such as peppermint, ginger, etc., may contain 50 per cent. or more of alcohol and are largely sold to the public for domestic uses. The alcohol provision might require that any medicine for internal use, of which the average dose is more than one teaspoonful (80 minims), if containing more than a given per cent. of alcohol, should be liable to all the conditions of sale, etc., of the ordinary distilled liquors.

Proprietary Medicines Discussed.

The New York County Medico-Pharmaceutical League at its last meeting held a symposium on "Proprietary Medicines." Some of the druggists held that they were compelled to carry mixtures of which they disapproved because some physicians prescribed them. From the standpoint of the manufacturer, Frederick Mason and Benjamin T. Fairchild stated that through better machinery and greater quantities of material they could do better than the apothecary in his shop. Dr. William J. Robinson and Dr. Heinrich Stern declared that certain manufactured drugs were known as staples to be trusted, but that there are many which are not even to be experimented with.

Commendations of the Fight Against Nostrums.

Dr. Albert S. Barnes, Bokins, Ohio, writes, under date of January 16:

"I am glad to note the awakening in *THE JOURNAL*. I hope the time will speedily come when all who read *THE JOURNAL* or advertise in it will know assuredly that it stands for ethics, means to be ethical, and is ethical; and that so it will champion the cause of legitimate medicine and honorable practitioners against all fakes and fakers, whether within or without the profession."

Dr. E. B. Partin, Chunky, Miss., January 16, writes:

"I am well pleased with *THE JOURNAL* and as president of our county (Newton) society can say that we fully indorse your course in regard to 'patent' and proprietary medicines. A bill now before our legislature will very likely pass in regard to this growing evil."

Dr. F. W. Taylor, Provo City, Utah, writes, January 12:

"Your articles on the patent and proprietary medicines (as well as those in several lay journals) are certainly working wonders among the members of the general medical profession, causing them to think for themselves and to discard the ready made and highly seasoned therapeutics that have been almost daily forced on them by the dealers."

"Continue the good work and do not cease your efforts until deception and graft have been overthrown. You certainly have the whole medical profession behind you and with such a sustaining force wonders can and will be accomplished."

"Wishing you success in your fight for right, your educative measures, and your high ideals."

Dr. Richard F. Rand, New Haven, Conn., writes, January 20:

"Allow me also to express my appreciation of your efforts in the crusade against the nostrum evil. I hope you will continue your suggestions for treatment along the line of standard therapeutics."

Dr. W. H. Ensworth, Boston, writes January 17:

"The two reasons that I subscribe at this time are: First, the fact that the next meeting of the American Medical Association is to be held in Boston; second, the stand you have taken on the question of the use of proprietary medicines."

"The latter is the more important and is the deciding reason with me. Laziness or ignorance is the only imaginable excuse for such use. Usually it is both, with one or the other predominating. I trust that you will keep on with the good work."

At a meeting held January 3, the Suffolk District Section of the Massachusetts Medical Society passed resolutions indorsing the action of the American Medical Association in establishing a Council on Pharmacy and Chemistry, and approving the work done by the Council. The society also commended the work done by *THE JOURNAL*, *Collier's Weekly* and the

Ladies' Home Journal in exposing the methods of the Proprietary Association and showing up the fraudulent use of sham testimonials and the loss of life due to the use of products exploited by members of that association. Similar resolutions were passed by the Tippecanoe County (Ind.) Medical Society, the Jackson County (Mo.) Medical Society, the Jefferson County (Ala.) Medical Society, and the Delaware County (Pa.) Medical Society.

The Gibson County (Ind.) Medical Society, at the regular meeting, held January 26, adopted the following resolutions:

Resolved, That in view of the rapidly increasing patent and proprietary nostrum evil being imposed on the people and exploited among physicians of the country, it becomes our duty and pleasure heartily to approve the action of the American Medical Association in establishing a Council on Pharmacy and Chemistry.

Resolved, That we urge THE JOURNAL of the American Medical Association to continue its campaign of educating its readers in the use of official drugs and remedies.

Resolved, That we heartily approve the stand taken by *Collier's Weekly* and the *Ladies' Home Journal*, in their attempt to arouse in the public conscience a just appreciation of the nostrum evil, and the manner and means used to coerce the public press to exploit these goods and to oppose the passage of any laws that would compel the fixing of a label on each package whereby the public might know what it is taking.

Resolved, That a copy of these resolutions be sent to THE JOURNAL of the American Medical Association, to *Collier's Weekly* and to the *Ladies' Home Journal*.

No Longer Members of the Proprietary Association.

We have been notified by the Cystogen Chemical Company, St. Louis, that they have resigned from the Proprietary Association of America.

Messrs. Schlottbeck & Foss Company, Portland, Maine, have also notified us that they have withdrawn from the Proprietary Association.

Another Country Newspaper Taking the Right Stand.

The *Ashland* (Neb.) *Journal* declares that it will not take advertisements from fraudulent patent medicine companies. It expresses its indignation over the fact that newspapers which should stand as defenders of the home accept the advertisements of these frauds and help them reach their victims. The editor admits that some testimonials are genuine and that some persons are helped by these nostrums, but he calls attention to the fact that the same can be said about whisky, and that both the nostrums and whisky are responsible for thousands of dishonored graves, wrecked lives, ruined homes and broken hearts. The editor says further that his paper "needs advertising as badly as any paper in the state, but it does not need it badly enough to accept one line that it does not believe is thoroughly reliable, and we have no space for any medicine we do not know to be absolutely reliable."

"*Ashland* has a number of physicians whose abilities and characters stand unquestioned. We have drug stores where absolute honesty and accuracy are beyond doubt. Our physicians and druggists are men whom one can trust with the health and welfare of his loved ones with perfect confidence that the trust will be regarded as sacred and holy—men who would not endanger the lives of their patients for any amount.

"Health is the most precious blessing of this life, and we can not guard it too carefully. Don't risk it with patent medicines put up by strangers. Go to your home doctor."

Alcohol in "Patent Medicines."

A bill relating to alcohol in patent medicines has been introduced in the Massachusetts legislature. Last year a similar bill was defeated in the state senate. This year's bill (House No. 231) accompanying the petition of Representative W. Rodman Peabody for legislation to require that the percentage of alcohol in patent or proprietary medicines or foods shall be stated on bottles or packages thereof, provides that "on every package, bottle or other receptacle holding any proprietary or patent medicine, or any proprietary or patent food preparation, which contains alcohol to an amount exceeding 3 per cent, by volume thereof, there shall be marked or inscribed a statement of the percentage of alcohol by volume contained therein; and that whoever manufactures, sells or offers for sale any medicine or food preparation in violation of the provisions of this act shall be punished by a fine of not less than five nor more than one hundred dollars."

Marriages

ARTHUR MCGUGAN, M.D., to Miss Lucia Owen, both of Denver, January 24.

PAUL H. KEYES, M.D., to Miss Esther Collier, both of Dana, Ind., January 11.

G. W. DENCKLE, M.D., to Miss Ida E. Homstead of Newport, Iowa, January 16.

ABRAM B. FLEEGER, M.D., to Miss Etta M. Taylor, both of Cairo, Mo., January 17.

J. T. MILES, M.D., Bryant, Ind., to Mrs. Mary Addington of Geneva, Ind., January 15.

FRANCIS F. H. SULLIVAN, M.D., to Miss Ethel Caschott, both of Miami, Mo., January 13.

WALTER S. KING, M.D., Cedar Rapids, Iowa, to Miss Mabel Gravatt of Tracer, Iowa, January 17.

F. M. BRUCE, M.D., Pineview, Ga., to Miss Annie Pearl Mitchell of Abbeville, Ga., January 7.

A. SPENCER KAUFMAN, M.D., Philadelphia, to Miss Florence Fox of Lock Haven, Pa., January 24.

HEBER L. CLEVELAND, M.D., Orange, Mass., to Miss Mary Elizabeth Reed of Toledo, Ohio, January 17.

JOSEPH VON C. ROBERTS, M.D., Philadelphia, to Mrs. Grace F. Reynolds of Middletown, Del., January 23.

HAWKINS BISHOP, M.D., Burnside, Ky., to Miss Lura Lipp of Hustonville, Ky., at Lexington, Ky., January 24.

WILLIAM WHITEHEAD GIFFELAN, M.D., New York City, to Mrs. Mary Louise Hayes of Newark, N. J., January 25.

E. LAWRENCE MEYER, M.D., Walnut Grove, Minn., to Miss Margaret Emerson Dinsmore of Minneapolis, January 17.

LIEUTENANT JOHN ALEXANDER CLARK, M.D., United States Army, to Miss Anna Nicholson Scott, at Washington, D. C., January 26.

Deaths

Berthold B. Pirosh, M.D. University of St. Petersburg, Russia, 1877; a member of the American Medical Association, Illinois State Medical Society, Chicago Medical Society, and the German Medical Association; professor of electrotherapeutics in the College of Physicians and Surgeons, Chicago; a member of the United Hebrew Charities, and a member of the medical staff of the Orthodox Home for Aged Jews; by reason of his activity in behalf of Jewish immigrants, known as the "father of the Russian Jews," died at his home in Chicago, January 25, from pleurisy, after an illness of seven months, aged 52.

John W. Long, M.D. Bellevue Hospital Medical College, New York City, 1865; of Bryan, Ohio; acting assistant surgeon in the Army for three years; a member of the American Medical Association, and of the Ohio State Medical Society, Northwestern Ohio Medical Society and Williams County Medical Society; local surgeon of the Lake Shore & Michigan Southern Railway for more than thirty years, died at St. Joseph's Hospital, Chicago, from heart disease, while under operation for malignant disease of the throat, January 23, aged 71.

Adelbert D. Head, M.D. Albany (N. Y.) Medical College, 1866; a member of the American Medical Association; one of the founders of the New York State Medical Association; a member of the Syracuse Academy of Medicine; a veteran of the Civil War; one of the best-known practitioners of Syracuse, N. Y., died at his home in that city, January 21, from diabetes, after an illness of nearly a year, aged 63.

Norman R. Miller, M.D. College of Physicians and Surgeons in the City of New York, 1882; a member of the Massachusetts Medical Society; for several years medical director of a sanitarium in Lynn, Mass., died recently at the Western Insane Hospital, from brain disease, after an illness of more than a year.

James Marion Walker, M.D. University of Louisville (Ky.) Medical Department, 1848; St. Louis Medical College, 1855; died at the home of his son-in-law, Dr. J. Y. Hume, Armstrong, Mo., from carcinoma of the right shoulder, Dec. 8, 1905, after an illness of about two years, aged 81.

Simon A. Freeman, M.D. University of Buffalo (N. Y.) Medical Department, 1869; hospital steward during the Civil War; acting assistant surgeon, United States Army, from 1870 to 1879; for many years in business in Everett, Mass., died recently at his home in California.

Charles C. Parker, M.D. Starling Medical College, Columbus, Ohio, 1850; late demonstrator of anatomy in that institution; surgeon of the Twelfth Iowa Volunteer Infantry in the Civil War; for four years trustee of the Iowa Hospital for the Insane, Independence, and for many years a trustee of the Upper Iowa University, died suddenly at his home in Fayette, Iowa, January 14, aged 82.

Thomas B. Potter, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1851; assistant surgeon of the Seventy-seventh Pennsylvania Volunteer Infantry in the Civil War; at one time Burgess of Phillipsburg, Pa.; died at his home in that place, January 12, from disease of the kidneys, after an illness of ten weeks, aged 76.

William B. Neftel, M.D. University of St. Petersburg, Russia, 1852; a member of the Medical Society of the County of New York, New York Academy of Medicine, New York Pathological Society, and Physicians' Mutual Aid Association; a specialist on nervous diseases, died at his home in New York City, January 20, aged 75.

Artemus L. Hersey, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1853, for more than half a century a practitioner of Oxford, Maine, and for several years superintendent of schools, died at the home of his daughter in Boston, January 12, from cerebral hemorrhage, after an illness of two days, aged 79.

Frank H. Caldwell, M.D. Jefferson Medical College, Philadelphia, 1880; a member of the American Medical Association; for more than 20 years a practitioner of Florida, and for several years chief surgeon in that state for the Plant System, died at his home in Tampa, January 20, from nephritis.

John Martin Knick, M.D. Medical College of the State of South Carolina, Charleston, 1905, an interne at the Kingsdon Avenue Hospital for Contagious Diseases, Brooklyn, N. Y., died at that institution, January 19, from scarlet fever, after an illness of six days, aged 22.

William H. Harrison, M.D. Bellevue Hospital Medical College, New York City, 1864, assistant surgeon of the Fourth Wisconsin Volunteer Cavalry during the Civil War, died at his home in Brunner, Texas, January 19, from nephritis, after an illness of a year, aged 65.

Edward Williams, M.D. Medical College of Virginia, Richmond, 1856, a member of the Dan River district school board as well as prominent in county affairs, died at his home in Malmaison, Va., January 20, after an illness of a year, aged 72.

Julian Perault, M.D. Faculty of Medicine of Queen's University, Kingston, Ont., 1857, a pioneer physician of San Francisco, died at the home of his daughter in Alameda, January 15, from cerebral hemorrhage, after an illness of 19 days.

Howard O. Smith, M.D. Vanderbilt University Medical Department, Nashville, 1892, formerly of Alpine, Quanar and Hamilton, Texas, died from tuberculosis at Guadalajara, Mexico, January 12, after an illness of several years.

George H. Carpenter, M.D. Vermont Medical College, Woodstock, 1842, surgeon of the Ninety-first Ohio Volunteer Infantry in the Civil War, died at his home in Cleveland, January 21, after an invalidism of several years, aged 85.

Charles Stuart Tripler, M.D. University of Paris, France, 1866, of Cronwell, a veteran of the Civil War, died at the Fannie Paddock Hospital, Tacoma, from septicemia, after an illness of several weeks, aged 59.

Milton Baker, M.D. Trinity University and Trinity Medical College, Toronto, 1894, of Brantford, Ont., died in the Brantford General Hospital January 23, from middle-ear disease followed by meningitis, aged 38.

Pleasant B. Cross, M.D. Eclectic Medical Institute, Cincinnati, 1872, a veteran of the Civil War, died at his home in South Webster, Ohio, January 22, from pneumonia, after an illness of one week, aged 62.

Louis Thompson Sturgis, M.D. Rush Medical College, Chicago, 1882, a well-known physician of Fort Wayne, Ind., died at his home in that city, January 15, from nephritis, after an extended illness, aged 57.

Hannibal Hamlin, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1872, chairman of the board of selectmen of Orono, Maine, died at his home in that place, January 19, from peritonitis, aged 58.

J. W. Oslin, M.D. Medical College of Georgia, Augusta, 1854, for many years local surgeon of the Southern Railroad, died at his home in Gainesville, Ga., January 9, after an illness of several weeks, aged 78.

Franklin P. Sigworth, M.D. College of Physicians and Surgeons, Baltimore, 1883, died at his home in Craneyville, Pa.,

January 8, from accidental poisoning by fluid extract of aconite, taken in mistake for cough syrup, twenty-four hours before, aged 50.

Edwin Dudley Smith, M.D. Eclectic Medical College of the City of New York, 1876, died at his home in Springfield, Mass., January 4, after an illness of ten months, from valvular heart disease, aged 72.

William Hillhouse, M.D. New York University, New York City, 1845, once tax collector of New Haven, Conn., died at the home of his son in that city, January 17, from cerebral hemorrhage, aged 85.

Joseph A. Coffman, M.D. Kentucky School of Medicine, Louisville, 1890, of Poetry, Texas, fell from a railroad trestle at Terrell, Texas, January 18, and died the next morning from his injuries.

Charles Wesley Bayley, M.D. University of Vermont Medical Department, 1876, formerly of Oakdale, Cal., died at his home in San José, Cal., January 9, after a prolonged illness, aged 60.

John Frederick Brine, M.D. Harvard University Medical School, Boston, 1868, medical health officer for the Commercial Cable Company, died at Hazel Hill, Nova Scotia, January 18.

Edmund H. Evans, M.D. Jefferson Medical College, Philadelphia, 1889, died at his home in Philadelphia, from Bright's disease, January 26, after an illness of two years, aged 45.

Frank Parker Perry, M.D. Long Island College Hospital, Brooklyn, N. Y., 1873, died at his home in Bucksport, Maine, January 14, from paralysis, after a long illness, aged 55.

William Anderson Payne, M.D., formerly of New York City, a member of the Bexar County (Texas) Medical Society, died suddenly in his office in San Antonio, January 10, aged 32.

Frederick W. Lapsley, M.D. Detroit (Mich.) College of Medicine, 1892, surgeon during the Spanish-American War, died recently in Chicago, from pneumonia, aged 36.

Albert G. Sisson, M.D. Vanderbilt University Medical Department, Nashville, 1879, died suddenly at his home in Wills Point, Texas, January 9, from heart disease.

Alfred S. Patrick, M.D. Medical College of Ohio, Cincinnati, 1853, died at his home in Charleston, W. Va., January 23, after an illness of four weeks, aged 74.

William O. Powell, M.D. (Illinois State Board of Health), 1887, once postmaster of Mackinaw, Ill., died suddenly, January 23, while hunting near Mackinaw.

George Gaines Lyon, M.D. Pulte Medical College, Cincinnati, 1888, of Mobile, Ala., died in Chicago, January 17, from paralysis, after a prolonged illness, aged 45.

Columbus W. Osburn, M.D. Cincinnati College of Medicine and Surgery, 1871, died at his home in West Lebanon, Ind., January 11, after a long illness.

William John Early, M.D., member of the College of Physicians and Surgeons of Ontario, 1889, died at his home at Owen Sound, Ont., January 25.

M. C. Johnson, M.D. Kentucky School of Medicine, Louisville, 1880, died at his home in Ghent, Ky., January 23, from heart disease, aged about 60.

John McClellan, M.D. Jefferson Medical College, Philadelphia, 1836, died at his home in Woodstock, Conn., Dec. 19, 1905, from senile debility, aged 93.

L. B. Selvidge, M.D. Missouri Medical College, St. Louis, 1884, died at his home in Collins, Mo., January 6, from pneumonia, after a short illness.

Isaiah Williams, M.D. Eclectic Medical Institute, Cincinnati, 1853, died at his home in Clarence, Iowa, January 7, after a long illness, aged 85.

Henry S. Kelley, M.D. Ensworth Medical College, St. Joseph, Mo., 1893, died at his home in Fillmore, Mo., January 12, from pneumonia, aged 35.

Joseph Hancock, M.D. Hahnemann Medical College, Philadelphia, 1878, died at his home in Philadelphia, January 19, aged 54.

Amacey B. Abell, M.D. Jefferson Medical College, Philadelphia, 1875, died at his home in Philadelphia, January 24, aged 62.

Deaths Abroad.

Jose Esteve, M.D., of Murcia, Spain, died at an advanced age early in January. He was a very popular physician, president of the local academy of medicine, and had taken a prominent part in political life. All the stores in Murcia were closed on the day of his funeral, and his body was escorted to the tomb by a concourse of ten thousand mourners.

Book Notices

NEW YORK STATE LIBRARY. Yearbook of Legislation, 1904. Edited by E. H. Whitton. Sociology Librarian. Cloth. Price, \$1.00. Albany: New York State Education Department, 1905.

This yearbook furnishes a practical guide to American legislation, most useful to publicists, legislators, executives and others interested in any specific movement or in the general trend of legislation. It includes an index of legislation, briefly indexing or summarizing 2,190 laws and constitutional amendments. There is also a review of legislation made up of the contributions of forty specialists from all parts of the country, each reviewing the year's progress in his particular field.

ANATOMY AND PHYSIOLOGY FOR NURSES. By L. Lewis, M.D. Illustrated. Cloth. Pp. 317. Price, \$1.75 net. Philadelphia: W. B. Saunders & Co., 1905.

Dr. Lewis has confined himself to information really necessary for nurses and, unlike many authors, has not digressed from his subject. The text is clear and concise and the illustrations are good. At the end of each chapter there is a list of review questions which should prove of value to nurses using this book.

Queries and Minor Notes

SWEET SPIRITS OF NITER.

JAKIN, GA., Jan. 19, 1906.

To the Editor:—I would like to know whether or not sweet spirit of niter is of any use after it turns acid. Potter's *Materia Medica* says: "It soon turns acid on standing, and should not be kept long." I have a great deal of trouble getting it sweet, and on making complaint to my druggist about a package received that was intensely acid, he replied that the article was C. P., and all right, that the name sweet spirit of niter did not indicate that it was sweet, and that I could add a small quantity of bicarbonate of soda to blunt the sharpness. When fever mixtures are made with the acid stuff, it effervesces with potassium citrate, and does not that destroy the properties of the latter drug? Please state the facts in regard to this matter and oblige. H. G. MINTER.

ANSWER.—Spirit of nitrous ether was called "sweet" spirit of niter to emphasize the fact that when pure and fresh it should have an agreeable sweetish taste. It is a solution in alcohol of nitrous ether, which is ethyl nitrite with some other products derived in the making. This nitrous ether may be kept for a considerable time without change in alcoholic solution, but on exposure, or on dilution with water, or watery mixtures, it is rapidly decomposed. This is what happens to the spirit which often contains water and, therefore, turns acid, loses its strength and becomes unfit for use. To neutralize the acid by placing a crystal of potassium bicarbonate in the bottle is of course simply a makeshift. When spirit of nitrous ether effervesces with alkalies, it is valueless and should be replaced by a fresh supply. The only way to insure a fresh article is to obtain the spirit in original one-pound bottles of well-known make, and then to keep it in a cool, dark place in a tightly stoppered container. The concentrated nitrous ether may also be obtained in hermetically sealed glass-tubes which on dilution with alcohol produces at once a fresh and full strength spirit.

FOREIGN BODIES SWALLOWED AND SAFELY EXPELLED FROM THE INTESTINE.

TUCSON, ARIZ., Jan. 16, 1906.

To the Editor:—Referring to the reports of cases published by Drs. L. W. Little and J. A. Postlewait, in *THE JOURNAL*, Nov. 25, 1905, and Jan. 12, 1906, I would say that I have seen such articles passed by infants not infrequently. A few weeks ago a child of fifteen months swallowed a shawl pin, 3 inches in length and having on one end a glass head, slightly more than a quarter of an inch in diameter. The pin was passed intact after exactly six weeks. There were no symptoms in the interval. In another case, an adult, with a large abdomen, swallowed a fish bone which in the course of about three months ulcerated out through the abdominal walls, making its appearance just below the umbilicus. In this case, there followed an intraperitoneal abscess, which was opened, the patient making a good recovery. Such articles as opened safety pins, brooches, etc., passed safely through the intestinal tube must be encountered by every man with a large general practice. MARK A. ROGERS, M.D.

THORNVILLE, OHIO, Jan. 19, 1906

To the Editor:—In *THE JOURNAL*, Jan. 13, reference is made to two cases of infants swallowing safety pins. A case equally, if not more interesting, came under our observation during the past summer. A child of 6½ months swallowed an open safety pin measuring one inch in length and half inch at angle of opening. The pin was swallowed on the evening of June 29 and was discovered by the mother in the child's diaper on the morning of July 17. The

case is remarkable on account of the age of the child and the length of time the pin took to pass through the intestinal tract. The child suffered no inconvenience and needed no treatment. G. W. and P. R. CLEMONS.

PHENOL AND FORMALDEHYD STERILIZATION.

—, IOWA, Jan. 19, 1906.

To the Editor:—1. Can knives be thoroughly sterilized in phenol? 2. Can dressings be thoroughly sterilized by formaldehyde vapor? If so, how? H. E. C.

ANSWER.—1. Knives can be thoroughly sterilized in 95 per cent. phenol solution. They should be rinsed in absolute alcohol before being used. 2. Yes, if the dressings are in sealed packages loosen them so as to be easily penetrated by the fumes. Place them in a receptacle in which the vapor can be generated and leave it closed a few hours after filled with the vapor. Formaldehyde sterilization of dressings is not very practical, as the vapor renders the dressings irritating, not only to the wounds, but also to the skin. To allow the dressings to remain spread out so that the vapor may escape might endanger recontamination. Steam sterilization is the best for dressings.

State Boards of Registration

COMING EXAMINATIONS.

NEBRASKA State Board of Health, State House, Lincoln, February, 7 S. Secretary, George H. Brash, Beatrice.

Louisiana November Report.—Dr. F. A. Larue, secretary of the Louisiana State Board of Medical Examiners, reports the written examination, held at New Orleans, November 14-15, 1905. The number of subjects examined in was 10; total number of questions asked, 50; percentage required to pass, 75. The total number of applicants examined was 22, of whom 16 passed and 6 failed. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
Cornell University	(1905)	94.4
Women's Medical College of Pennsylvania	(1905)	84.8
University of Arkansas	(1905)	83.8
Baltimore Med. College	(1901)	83.2
University of St. Louis	(1905)	80.2
University of Palermo, Italy	(1900)	87.4
Northwestern University	(1905)	80.6
University of the South (1890)	92; (1904)	75.4; (1905)	81.4.
S. S., 87.6.			
Fulane Medical College	(1905)	78.4, 88.5
University of Illinois	(1904)	80.6
Flint Medical College*	(1905)	80.4

FAILED.

TABLE I.			
Louisville Medical College	(1905)	72.0
Kentucky School of Medicine	(1898)	65
Memphis Hosp. Medical College	(1893)	66
University of Georgia	(1889)	74
Flint Medical College*	(1904) 69.8; (1905)	66

* Colored.

Maryland December Report.—Dr. J. McPherson Scott, secretary of the State Board of Medical Examiners, reports that 31 of the 60 candidates who took the examination in December, passed successfully and received licenses.

Michigan.—Dr. Beverley D. Harrison has announced the removal of the office of the State Board of Registration in Medicine from Sault Ste. Marie to 303 Whitney Building, Detroit.

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending January 27:

Devereux, J. R., and Keller, Wm. L., asst.-surgeons, ordered to accompany Second Infantry from Fort Logan, Colo., to San Francisco. On completion of this duty to return to their proper stations. Asst.-Surgeon Keller, Fort Douglas, Utah, to report not later than the 23d inst., at Fort Logan, Colo.

Rockhill, Edward P., asst.-surgeon, advanced from grade of first lieutenant to captain.

Fort, Clyde S., asst.-surgeon, relieved from duty at Fort Barrancas, Fla., and ordered to medical supply depot, New York City, N. Y., for duty.

Asbush, P. M., and Craig, Charles P., asst.-surgeons, appointed members of a board of medical officers to meet at Manila, P. I., for the purpose of studying tropical diseases as they exist in the Philippine Islands. The board will be governed in its proceedings by such instructions as it may receive from the Surgeon General of the Army.

Snyder, Henry D., surgeon, ordered to Fort Reno, Oklahoma Territory, for purpose of investigating and reporting on administration of medical department at that post.

Clayton, J. B., asst.-surgeon, reported for temporary duty at Military Prison, Fort Leavenworth, Kans.

Scott, Geo. H., asst.-surgeon, granted thirty days' leave of absence when relieved from duty at San Francisco.

Haddock, H. M., surgeon, granted twenty-one days' sick leave of absence.

Gispiam, Wm. N., asst.-surgeon, leave of absence extended thirty days.

Gandy, Charles M., surgeon, ordered to accompany Headquarters and Second Battalion, First Infantry, from Fort Wayne, Mich., to New York City, and on completion of this duty to return to station.

Marrow, Chas. E., asst.-surgeon, ordered to proceed from Fort Sheridan, Ill., to Fort Brady, Mich., to accompany First Battalion First Infantry from that post to New York City, and on completion of this duty to return to station.

Cohn, J. M., asst.-surgeon, reported for duty at Army and Navy General Hospital, Fort Springs, Ark.

Reilly, John J., Shook, Jay L., Wilson, Compton, asst.-surgeons, ordered to report to Major William H. Arthur, president of examining board, Army Medical Museum Building, this city, for examination to determine their fitness for advancement.

Thorpe, Charles W., contract surgeon, granted sick leave of absence for one month.

Carson, Samuel K., contract surgeon, ordered to Fort Jay, N. Y., for temporary duty.

Brooks, John D., contract surgeon returned to Fort Meads, S. D., from leave of absence.

Hall, Henry M., contract surgeon, ordered to temporary duty at Fort McDowell, Cal., on the completion of which duty he will proceed home, Cedartown, Ga., for annulment of contract after leave of absence for two months.

Milikin, John H., dental surgeon, granted ten days' leave of absence.

Wolven, P., Homer, dental surgeon, left Fort McKinley, Me., and arrived at Fort Peble, Me., for duty.

Long, Charles E., dental surgeon, ordered to visit, in succession, Forts Harrison, Mont.; Missoula, Mont.; Yellowstone, Wyo.; Keogh, Mont.; Lincoln, N. D.; Assiniboine, Mont.

Navy Changes.

Changes in the Medical Corps, U. S. Navy, for the week ending January 27:

E. L. Jones, asst.-surgeon, appointed assistant surgeon, with rank of lieutenant, junior grade, from Dec. 30, 1905.

Pace, J. E., surgeon, commissioned surgeon from April 20, 1904.

Dell, W. H., surgeon, commissioned surgeon from May 20, 1905.

Brown, E. M., P. A. surgeon, commissioned P. A. surgeon from May 8, 1905.

Baker, M. W., P. A. surgeon, commissioned P. A. surgeon from July 10, 1905.

Lays, J. P., surgeon, detached from the Bureau of Medicine and Surgery, Navy Department, and ordered to the Naval Hospital, Norfolk, Va.

Pickrell, G., surgeon, detached from duty in charge of the Naval Hospital, San Juan, P. R., ordered home, and granted sick leave for three months.

Murphy, J. E., P. A. surgeon, commissioned P. A. surgeon from May 18, 1905.

Holloway, J. H., P. A. surgeon, commissioned P. A. surgeon from September 26, 1905.

Schwerin, L. H., acting asst.-surgeon, appointed acting asst.-surgeon from Jan. 28, 1906.

Stokes, C. F., surgeon, detached from duty at the Naval Medical School, Washington, D. C., February 7, and ordered to duty in command of the Naval Hospital, San Juan, P. R., sailing from New York, N. Y., about February 10.

Frailsted, W. C., surgeon, detached from the bureau of medicine and surgery, Navy Department, February 7, and ordered to duty at the Naval Medical School, Washington, D. C., and to additional duty as a member of the anatomical board of the District of Columbia.

Tiebt, J. G., surgeon, detached from the *Celtic* and ordered home to wait orders.

Jones, E. L., asst.-surgeon, ordered to the Naval Hospital, Mare Island, Cal.

McDonald, W. N., asst.-surgeon, detached from the Naval Station, Culabra, W. I., and ordered to the *Matine* to temporary duty, and thence to the *Celtic*.

Hull, H. E., asst.-surgeon, detached from the Naval Hospital, New York, N. Y., and ordered to the *Celtic* for temporary duty, and thence to the Naval Station, Culabra, W. I., and to additional duty on the *Albatross*.

Public Health and Marine-Hospital Service.

List of changes of stations and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending January 27:

Gutierrez, G. M., surgeon, granted ten days' leave of absence from January 27.

Greene, J. E., P. A. surgeon, granted leave of absence for two months and twelve days from January 18.

Foster, M. H., P. A. surgeon, granted leave of absence for one month from January 23.

Richardson, T. P., P. A. surgeon, granted three months leave of absence from January 20, with permission to go beyond sea.

Richardson, T. P., P. A. surgeon, relieved from duty at Savannah, Ga., effective January 24.

Richardson, T. P., P. A. surgeon, excused from duty, without pay, from April 30, 1906, to Feb. 15, 1907, for the purpose of undertaking the sanitation of the North coast of the Republic of Honduras.

McKeon, E. H., asst.-surgeon, temporarily relieved at San Francisco Quarantine Station, and directed to proceed to Columbia River Quarantine Station for temporary duty.

Barthol, H. W., acting asst.-surgeon, granted leave of absence for twenty days, from January 20.

Stearns, W. L., pharmacist, granted extension of leave of absence for seven days, from January 20.

RESIGNATION.

Greene, J. E., P. A. surgeon, resigned to take effect, March 30.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon-General, Public Health and Marine-Hospital Service, during the week ended January 26:

SMALLPOX—UNITED STATES.

California: San Francisco, Jan. 6-13, 7 cases.
Colorado: Teller County, Dec. 1-31, 10 cases.
Florida: Jacksonville, Jan. 13-20, 5 cases; Alachua County, 1 case; Columbia County, 4 cases; Hillsboro County, Jan. 13-26, 12 cases; La Fayette County, Jan. 13-26, 6 cases.
Kentucky: Covington, Jan. 13-26, 6 cases.
Louisiana: New Orleans, Jan. 13-20, 1 case; Shreveport, 5 cases.
Maryland: Baltimore, Jan. 13-20, 4 cases.
Missouri: St. Louis, Jan. 13-20, 1 case.
Montana: Flathead County, Dec. 1-31, 1 case.
Ohio: Cincinnati, Jan. 12-19, 6 cases.
Virginia: Norfolk, Jan. 15, 5 cases; at Craney Island, 68.
Washington: Bellingham, Dec. 1-31, 8 cases; Covitz County, 7 cases; Spokane, 2 cases; Whitman County, 1 case.
Wisconsin: Appleton, Jan. 13-20, 2 cases; Milwaukee, Jan. 6-20, 2 cases.

SMALLPOX—INSULAR.

Porto Rico: San Juan, Nov. 1-30, present.

SMALLPOX—FOREIGN.

Africa: Cape Town, Dec. 2-9, 2 cases.
Brazil: Rio de Janeiro, Dec. 10-24, 3 cases, 1 death.
Canada: Toronto, Jan. 6-13, 1 case.
Chile: Antofagasta, Oct. 1-31, 51 deaths; Nov. 1-30, 27 deaths.
China: Hong Kong, Dec. 2-9, 1 case, 1 death.
Ecuador: Guayaquil, Dec. 10-17, 3 deaths.
France, Paris, Dec. 31-Jan. 6, 15 cases, 1 death.
Gibraltar: Dec. 24-Jan. 7, 12 cases, 1 death.
India: Bombay, Dec. 10-26, 6 deaths; Karachi, Dec. 17-24, 1 case.
Italy: Catania, Jan. 4-11, 3 deaths.
Mexico: Tuxpam, Jan. 9-16, 20 cases, 1 death.
Russia: Moscow, Nov. 11-23, 10 cases, 3 deaths; Odessa, Jan. 10-20, 25 cases, 3 deaths; St. Petersburg, Dec. 19-23, 26 cases, 3 deaths.
Spain: Barcelona, Dec. 21-31, 13 deaths.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, Dec. 10-24, 9 cases, 9 deaths.
Cuba: Havana, Jan. 16-22, 2 cases, 2 deaths.
Ecuador: Guayaquil, Dec. 10-17, 6 deaths.
Mexico: Orizaba, Jan. 7-13, 1 case, 1 death.

CHOLERA—INSULAR.

Philippine Islands: Manila, Dec. 2-9, 1 case, 1 death.

CHOLERA—FOREIGN.

Russia: Government of Louza, Dec. 18-21, 5 cases.

PLAQUE—FOREIGN.

Brazil: Rio de Janeiro, Dec. 10-24, 16 cases, 7 deaths.
China: Hong Kong, Dec. 2-9, 3 cases, 3 deaths.
India: Bombay, Dec. 19-26, 9 deaths; Karachi, Dec. 17-24, 17 cases, 12 deaths.
Japan: Kobe, Nov. 8-Dec. 8, 41 cases, 30 deaths; Osaka, Nov. 2-Dec. 8, 66 cases, 51 deaths.
Peru: Guadalupe, Nov. 20-Dec. 10, 2 cases; Lima, 7 cases; Trujillo, 3 cases.

Medical Organization

Kansas.

NEOSHO COUNTY MEDICAL SOCIETY.—With a charter membership of 22 this society was organized at Chanute. The following officers were elected: Dr. Ralph A. Light, Chanute, president; Dr. John C. Lardner, Chanute, vice-president; Dr. L. D. Johnson, Chanute, secretary and treasurer; Drs. William E. Barker and J. B. Edwards, both of Chanute, delegates to State Society, and Drs. F. W. Jones, Earleton; G. W. Morgan, Kimball, and Orlando M. Edwards, Chanute, censors.

Louisiana.

TERRE PARISH MEDICAL SOCIETY.—This society entered into permanent organization at Farmerville, Dec. 19, 1905, and elected the following officers: Dr. Charles H. Jameson, Farmerville, president; Dr. William Sellers, vice-president, and Dr. Royal L. Love, Mosely's Bluff, secretary and treasurer.

Oklahoma.

COMANCHE COUNTY MEDICAL AND SURGICAL SOCIETY.—This society was recently organized at Lawton, with Dr. Lavin C. Kneer, president, and Dr. Maud N. Mead, secretary, both of Lawton.

ST. CLOUIS COUNTY OKLAHOMA MEDICAL ASSOCIATION.—Under this name the physicians of Greer, Washita, Kiowa and Custer counties organized at Cordell, January 17. The following officers were elected: Dr. W. L. York, Hobart, president; Drs. A. W. Holland, Hobart, and James Hempstead, Arapahoe, vice-presidents; Dr. Alfred H. Bangard, Cordell, secretary, and Dr. T. J. Dodson, Mangum; W. J. Kerley, Cordell; W. W. Miller, Catoche; William Tidball, Barton; James Hempstead, Arapahoe, and James M. Bonham, Hobart, censors.

What Can the County Society Do?

IX. CO-OPERATE WITH THE HEALTH OFFICER.

Every county medical society should be actively interested in the appointment of municipal boards of health and health officers. A committee—the public relations committee usually—made up of strong and tactful members, should gradually make the political forces feel that the organized profession has a vital though perfectly unselfish interest in these appointments. Having secured good health officials and proper ordinances, there should be constant and complete co-operation between the society and the authorities.

In Cleveland, during the epidemic of smallpox, the committee of public health of the Academy of Medicine held weekly or daily meetings, as the occasion demanded, lending every possible aid to securing the complete vaccination of the citizens. The service rendered was so valuable and so evident that before long the mayor publicly and officially designated the members of the committee as an advisory board to the health officer.

Something of this sort is everywhere possible if the officials are considerably approached, a more recent instance having occurred at Natchez, where a society committee did splendid service during the epidemic of yellow fever.

X. DUTY OF REPORTING INFECTIONS.

One of the most difficult and embarrassing duties of a physician, and at the same time one of his most essential and responsible tasks is that of reporting cases of infectious disease. The patient and his family so earnestly desire concealment that the physician's position is most uncomfortable, but modern science has no hesitation in saying that his highest duty is to the community. Among the Italians in New Orleans a physician who reported a case of yellow fever was promptly discharged from attendance on all Italian cases. Yet Surgeon White, United States Public Health and Marine-Hospital Service, lays down the dictum: "A case of yellow fever known is a case of yellow fever extinguished." This truth was amply demonstrated at New Orleans during the past summer, and never again should it be necessary to fine physicians for failure to report cases. Preventive medicine is helpless in the face of epidemic disease unless every physician early recognizes and promptly reports every suspicious case.

In consequence it is the duty of the county medical society—the well-organized society that embraces within its membership every available physician in the county—to face and discuss this subject with a view to having every member recognize his solemn obligation to the commonwealth and to medicine. The proper support of the notification ordinance that every community should enact, it is easy to see, becomes a light task when there is complete unanimity among the physicians. Having, after consideration, agreed together to report every case of infection, the unreasonably citizen will learn that discharging his physician will not aid in concealment, and there will be an end to the application of the boycott to those physicians who do their duty. In many communities it will be feasible for the members to adhere to a "gentleman's agreement" to see that due punishment is administered to every member who is caught failing in this duty. It should be further agreed among the members that they will procure the punishment of all practitioners outside the society who conceal infectious cases. The execution of this plan will in a short time prove to be a great boon to the community, and will correspondingly increase the public respect for our profession.

The general action of the county societies on this question means something of vital moment to society, for such unanimous obedience to a good notification ordinance signifies that old-fashioned quarantine may forever be abolished.

Society Proceedings

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Regular Meeting, held Jan., 30, 1905

The President, DR. JAMES M. ANDERS, in the Chair.

Chronic Acetanilid Poisoning, with Report of a Case Due to Absorption of the Drug from a Leg Ulcer.

DR. JAMES B. HERRICK, Chicago, read a paper with the above title which appears in this issue of THE JOURNAL, page 351.

DISCUSSION.

DR. ALFRED STENGEL spoke of the necessity of distinguishing between acute acetanilid poisoning, which is exceedingly common, and chronic acetanilid poisoning, which is rare. His experience is limited to five cases, three of which he had examined; two others he had seen, but was not permitted to report. The first case was one similar to that reported by Dr. Herrick. There were the marked changes in the blood, such as he had not seen in any other case, the very marked change in the character of the red corpuscles, with the very decided tendency to nucleated red corpuscles. The case was that of a young girl brought to the University Hospital to be under the care of Dr. Matthew H. Cryer for trifacial neuralgia. On her arrival from Connecticut she was in such a desperate condition that surgical treatment was not warranted and she was put under medical inspection. She was extremely cyanotic. By direction of Dr. Stengel, she was bled to the extent of six or eight ounces. Dr. C. Y. White was convinced of the presence of acetanilid poisoning and soon convinced Dr. Stengel of the truth of his theory. After investigation it was found that the girl was surreptitiously receiving acetanilid capsules and she afterward confessed. The case was one of those diagnosed as congenital heart disease. The diagnosis had been made by a distinguished clinician who, it was suggested, was a good deal occupied and had made a more or less casual examination. Among several other diagnoses which had been made of the girl's condition was that of mediastinal tumor. That such mistaken diagnoses should have been made was not a surprise, owing to the most remarkable changes through which the heart passed. It increased tremendously in size. She had had several attacks of acute dilatation with the appearance and subsequent disappearance of a loud systolic murmur, with corresponding increase and subsidence in the intense cyanosis. With the intense cyanosis the extremities were warm. This was one of the first features suggesting the true nature of the case. Dr. Stengel expressed his belief that such changes in the heart could not be produced without serious damage to the musculature. To have a heart suddenly dilate and spread an inch or an inch and a half, beyond peradventure of a doubt, and then pull itself together on the cessation of the drug and the cyanosis disappear, he felt could not but leave some impression on the heart.

Interesting features were presented in the two other cases he had examined. In one, that of a very intelligent man, there were symptoms of cyanosis of the fingers and lips, with a sort of steel-blue color of the skin. The man had been taking "Phenolgin" and showed what Dr. Herrick had called a peculiar moral perversity: When under the influence of the drug he denied taking it; when not under its influence, he was willing to confess his use of it. The third case was that of a woman who secured the drug without the attending physician's knowledge. Dr. Stengel's diagnosis was proved to be correct. While under his care he found it possible to induce cyanosis, which disappeared readily when the drug was stopped.

Aside from these intense cases, Dr. Stengel believes with Dr. Herrick in the existence of a large number of cases of acetanilid poisoning of minor grade. In his own practice he has seen cases of disturbance of heart action and of general health which he believed due to frequent ingestion of the drug in sufficient amounts to interfere with health. Because these are the cases most numerous, he believed them of the most importance to the profession. Here, again, he believed with Dr.

Herriek that if physicians were on the alert the cases would not be difficult to recognize. He admitted the possibility of their being mistaken for a number of conditions detailed by Dr. Herriek.

Dr. S. SOLIS COHEN continued the thought expressed by Dr. Stengel that the physician should be constantly on the watch for the minor grades of acetanilid poisoning. In cases presenting ill-assorted and vague symptoms, explanations other than the true one might be given, unless some knowledge of the history, or unguarded remark of the patient directed attention into the right channel. He recalled the case of a very intelligent man who had been under his care for a number of years who had originally had attacks of migraine which he had himself treated by tablets bought at any drug store, these headaches and attacks of vomiting had been completely relieved by the use of glasses prescribed by Dr. George M. Gould. This case was an instance of true migraine relieved by proper refraction, the existence of which was looked on with doubt by a good many neurologists. Some time after passing from under Dr. Cohen's observation, and while spending the summer in the mountains, he was suddenly attacked with fainting, and he was informed by the examining physician that he had acute Bright's disease. He returned promptly to Philadelphia. Dr. Cohen's examination of the urine discovered the urine to be free from albumin, casts and sugar. It was learned that the man had been taking, when he felt tired, some bromo-seltzer. A further study of the case convinced Dr. Cohen that it was one of chronic acetanilid poisoning. In another case recalled by Dr. Cohen, in which the patient had had chronic heart disease, for some time the cyanosis was out of proportion to the cardiac lesion and investigation showed the bromo-seltzer habit. He is convinced that bromo-seltzer is perhaps the most common and most dangerous cause of chronic acetanilid poisoning among intelligent people.

One of the great dangers of chronic poisoning with coal-tar products was pointed out to be the sudden yielding of the heart to some unusual strain. Dr. Cohen further recalled the case of a young woman who had persisted in taking antilumina, which had been originally prescribed for migraine. About a year after her marriage she died suddenly, following an apparently normal labor. The knowledge of the continued use of antilumina during pregnancy gave the clue to the cause of death. The cases were cited as illustrations of the widespread habit of taking coal tar products and of the hold which the habit takes on people, although warned against it. He pointed out the importance of recognizing the early changes resulting, and the importance also of not mistaking for serious organic disease of heart or kidneys the profound symptoms sometimes developed.

Dr. HENRY LUTTMANN called attention to the probability that under the condition of the new Pharmacopœia there would be an increase in the cases of chronic acetanilid poisoning. This was because the Pharmacopœia had put on its list the compound powder of acetanilid, which was expected to take the place of antilumina. He thought the motive had been to meet this very successful proprietary and others of its class. In his opinion it was bad judgment so to place it, since every pharmacist would feel at liberty to sell it for headaches. A few of the high-class pharmacists would sell phenacetin, but with the cheaper price of acetanilid the tendency would be to sell the latter. He recalled the statement of an English physician that many so-called rare diseases were possibly only exaggerated forms of common conditions, and that if physicians could learn to look for the marked symptoms they would find the disease to be far less common than supposed to be. He believed that the practice of taking these drugs was so excessive and so encouraged by prescribing druggists that many troubles were mistaken by physicians for conditions of real disease, whereas they were really conditions of acetanilid or other coal tar products poisoning.

Dr. H. C. WOOD, JR., thought that Dr. Herriek had made out a very good case of the non-existence of chronic acetanilid poisoning. It had seemed to him that Dr. Herriek's case, also that of Dr. Stengel, were those rather of a series of successive acute poisonings than of one chronic poisoning. There were

not shown any of the characteristic symptoms following chronic poisoning; for example, as in sulfonal, the persistence of the symptoms after the withdrawal of the drug, and no permanent injury wrought by the prolonged use of the drug. Moreover, it was noted that Dr. Herriek in his experiments had been unable to produce any serious pathologic lesion in animals by the prolonged use of the drug. The symptoms had occurred immediately following the administration of very large doses of the drug, and persisted because the drug was persisted in until the animal died. It seemed to him, therefore, much more logical to regard the cases as repeated attacks of acute poisoning following the repeated ingestion of the poison.

This, of course, had no bearing on the existence of the drug habit. He thought there was a distinction to be made between the existence of the drug habit and the existence of poisoning produced by that habit. A point of interest to him was the suggestion that the cyanosis had occurred as the result of the ingestion of acetanilid. He thought it was commonly held that cyanosis is due to the presence of methemoglobin in the blood. Dr. Herriek and others, however, had failed to find any methemoglobin in the blood. If this were present in small quantities its existence might be difficult to prove. On the other hand, if present in only small quantity it could not account for the marked degree of cyanosis in these cases. He, therefore, thought that the large degree of cyanosis must be ascribed to the acute dilatation of the heart and failure of circulation characteristic of poisoning by the drug. It had been shown by Singer that blood which has undergone chemical change with production of methemoglobin is not destroyed; that is, it is possible to restore hemoglobin to a corpuscle which has had its change of methemoglobin. The experiments of a German investigator have shown that in those cases in which the blood has undergone chemical change a larger proportion of oxygen will be taken up if the atmosphere is one of pure oxygen. He experimented with mice and found that in an atmosphere of pure oxygen they would withstand a dosage two or three times as large as a fatal dose. He also found that if he increased the pressure of the oxygen they would withstand a still larger dosage of the poison.

Dr. W. M. L. COPLIN had not seen a case of chronic acetanilid poisoning and had had little experience with the acute forms. He referred to researches made under his direction on the influence of the coal-tar products on the protoplasm of the red blood cells. The work was especially in connection with the anilin dyes, acetanilid and antipyrin. Such marked changes in the red blood cells were found that on the cover-glass the blood lacked the color of ordinary blood. A point of diagnostic value mentioned was the appearance of the exudates when present. Nothing was found characteristic of actual nephritis. In concurrent work done with carbolic acid renal changes were very marked. From Dr. Coplin's work on the spleen of animals he regards with some skepticism reported instances of cirrhosis of the liver. One experimenter in a large number of dogs had observed a single case of cirrhosis of the liver. Concerning the micro-chemical reaction of the blood, the research work did not prove satisfactorily that there was any morphologic change in the blood which was at all characteristic. The striking feature was that there was no change in the tingeability of the blood explaining this peculiar hue of the freshly-dried blood.

Dr. JAMES C. WILSON said that if the distinction suggested by Dr. Wood between repeated acute attacks and chronic acetanilid poisoning were to be observed, cases of the latter were indeed very limited. He cited his observation of a case showing the occurrence of a persistent symptom in a patient by whom large doses of acetanilid were taken every day. The patient, a man of about 24, under treatment for a couple of years for syphilis, had taken enormous doses of iodids. He had suffered much from headache, and there was noticed progressive tendency to cyanosis, which his attending physician tried to explain by some idiosyncrasy to the iodids. Coming under Dr. Wilson's care in the hospital, the character of the cyanosis and the cardiac symptoms with splenic enlargement led to the diagnosis of acetanilid poisoning. Investigation

showed that the patient had had migraine prior to the chance, and had formed the habit of taking different kinds of headache powders obtained from the apothecary. During the treatment for syphilis he had taken "Orangeine" powders, never less than six or eight, sometimes as many as eighteen or twenty. Attempts to withdraw the drug were followed by outbreaks of intense headache. With the substitution of small doses of morphia without the knowledge of the patient all the symptoms disappeared and he left the hospital without having taken either acetanilid or morphia for two or three weeks and without the knowledge that he had had morphia. The point made by Dr. Wilson was that brought out by Dr. Herricks; that in some of these cases the original cause of distress may disappear and be replaced by a similar continuous suffering arising from the use of the drug itself. In Dr. Wilson's case the ultimate withdrawal of the acetanilid was followed by complete cessation of the headache for which the patient had habituated himself to the drug.

Dr. DAVID L. EDSALL said that he had seen one case, whether coincident or otherwise, in which the man had developed chronic mental symptoms and had been placed in an asylum for the insane. He asked about the persistence of mental symptoms. In regard to the relation of the methemoglobin to the symptoms, in one case in which there was profound cyanosis examination of the blood and urine revealed nothing but oxyhemoglobin in the blood and in the urine and no methemoglobin. He said it was certain that the presence of methemoglobin was not a satisfactory explanation of the cyanosis. Reference was made to one authority on chemical analysis of urine who had cast much doubt on the existence of methemoglobinuria and who considered the vast majority of the reported cases due to erroneous observation. Dr. Edsall thought the same might be true of the blood.

Dr. W. E. ROBERTSON said that his experience had been limited to two cases, one an acute case in which the infection occurred from an acetanilid dressing, and in which the symptoms subsided on the withdrawal of the dressing; the other, a chronic case, and in this the blood picture was similar to that presented in the discussion. In the chronic case, notwithstanding the great cyanosis, there was no dyspnea. It resembled very much a marked case of polycythemia, in which the cyanosis is of intense degree.

In connection with Dr. Wood's reference to the cases being regarded as instances of repeated attacks of acute poisoning rather than of chronic poisoning, he cited one observer who had noted on the complete withdrawal of the drug the persistence of the symptoms and also of mental symptoms.

Dr. GRY HINSDALE said that in the early days of the use of acetanilid, when it was known by the name of antifebrin, he thought the drug was used much more freely and injudiciously by physicians than at present. He recalled the case of a young man with epilepsy, in whose treatment the remedy was used for two years, and this patient, on leaving the city for a year, had obtained a considerable amount, to be used continuously. On his return, while there was some cyanosis, no other bad effects were apparent. The effect on the epilepsy was not curative, but probably mitigating. At the present Dr. Hinsdale would hesitate to use the drug in the quantities in which it was formerly employed.

Dr. HANAUER was inclined to regard the criticism of Dr. Wood of the term "chronic" acetanilid poisoning as a just one. He thinks that probably the action in these cases should be looked on as accumulative, and yet he does not believe that it has been definitely decided now permanent the damage done is. It can not be stated, certainly, that the heart muscle was not more or less permanently damaged, nor that the blood-making organs would be restored to their normal function. Neither was there certainty concerning permanent mental effects. He replied to Dr. Edsall that he could not answer his question regarding permanent mental derangement following chronic acetanilid intoxication. Most patients recovered promptly on the withdrawal of the drug. From the records of some of the cases he had observed that the finding of methemoglobin was somewhat doubtful, and felt that the examination for its presence should be very carefully conducted before it was declared to exist.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Treatment of Obesity.

A correspondent desires us to outline a course of treatment for obesity in a patient who has no other symptoms.

In outlining a treatment for obesity, the causes must be carefully looked into. In certain instances there is something wrong with the metabolism, consequently in the treatment overeating, excessive drinking, sedentary life, increased consumption of fats and carbohydrates, must be carefully regulated. Not infrequently a history of gout or diabetes is obtained, or perhaps anemia in some form is present. The age of the patient must also be taken into consideration when a reduction of fat is to be considered. Young individuals can not withstand such great and rapid reductions as those further along in life. In any case, in reducing flesh a gradual reduction should be the rule, and when a patient has lost from ten to fifteen pounds, after being placed on a strict diet, the diet should be made more liberal for a time. We can not recommend the administration of any preparations in a general way without a complete knowledge of the individual case. Thyroid extract is a preparation which is a valuable agent in some cases in the reduction of fat. It may be given in 5-grain doses three or four times a day; its effect on the heart, circulation and nervous system must be carefully watched, as it is very liable to produce an increased nervous condition and to cause subjective symptoms of the heart. About all that can be recommended in this case is placing the patient on a system of diet purported to such reduction of fat. We would recommend that form of diet advised by Banting, Oertel, Elstein, Weir Mitchell or Yeo. Von Noorden, in Nothnagel's Handbuch, recommends the following diet list in such cases: At 8 o'clock 80 grams of lean cold meat, 25 grams of bread, one cup of tea, with milk and no sugar. At 10 o'clock one egg. At 12 o'clock one cup of strong broth. At 1 o'clock a small plate of meat soup, 159 grams of lean meat, flesh or fish; 100 grams of potatoes with salad; 100 grams of fresh fruit. At 3 o'clock one cup of black coffee. At 4 o'clock 200 grams of fresh fruit. At 6 o'clock one-quarter liter of milk with tea. At 8 o'clock 125 grams of cold meat or 180 grams of meat, raw and grilled, and eaten with radishes and salads; 30 grams of graham bread, and two to three teaspoonfuls of cooked fruit with sugar.

Management of Epilepsy.

In the management of epilepsy Thomas P. Prout, in *American Medicine*, recommends that the therapeutics be divided into medicinal, hygienic and dietetic. Since no two patients with epilepsy will present exactly the same outline for treatment, it must be necessary, therefore, to individualize. One patient, perhaps, will not be able to take care of certain articles of food which another may relish; one may have a heart lesion or a kidney complication, while another may possess a lymphatic diathesis with a persistent thymus. In those cases commencing late in life the possibility of a specific infection or of some condition capable of producing a sclerotic condition of the arteries must be taken into consideration. The possible existence of tonsils, adenoids or cysticerci must also be considered. For the purpose of ameliorating the seizures, Prout recommends the bromids as the most important preparations. Their use in epilepsy, as has been established by experiment, depends on their ability to diminish cortical irritability. The effect of the bromid depends not so much on the amount administered and eliminated by the system as on the amount retained in the system, consequently he advocates, as do other authors, the withholding of the sodium chlorid from the food and substituting for that salt the sodium bromid in the cooking. In such medication, however, it is evident there are great difficulties in regulating the size of the dose, and also there is

greater danger of bromid intoxication, as under this form of medication the patients are more susceptible to the drug. He speaks of the method advocated by Clark as a more practical one. The patient then receives a dosage of sodium bromid at regular intervals, and at the same time the meats and vegetables are either unseasoned or but slightly seasoned with salt. The patient, after the fashion of the English, can easily be taught to eat the butter unsalted.

The dosage of the bromids, which constitutes the general treatment of epilepsy, must be increased until the seizures are under control. When this point is reached the dose should be held at that level for some time, and then gradually reduced. In order to ward off the bad effects of this preparation on the system, the skin must be kept active and the bowels kept freely opened. There is one thing which he speaks of and which must be carefully guarded against, and that is the danger of reaching such a high dose as to produce marked irritating action on the stomach and sebaceous glands. One of the channels for the bromid elimination is the skin, which becomes more or less easily irritated by the elimination, and paralysis of the glandular structure may result with the retention of its secretion. This condition, according to Prout, may be overcome by active physical exercise and by baths. The latter is a very important adjunct to the treatment of epilepsy. The cold pack at 70 degrees and of from three-quarters to an hour in duration, followed by a short cold shower and vigorous rubbing, is recommended. However, the pack must be properly applied, and the shower bath must be short and sufficiently cold to give a distinct shock, and the rubbing afterward must be vigorous.

Exercise must be varied to suit the individual case; it may consist of field games, such as tennis and golf, or croquet, or, perhaps, dancing in moderation, and in winter horseback riding. Epileptics, almost without exception, are given to excesses in diet, and there is a desire, as a rule, for those articles which can not be properly digested. This tendency is still more pronounced in the insane epileptics. The author speaks of the possibility of reducing the seizures in epilepsy fully one-third or one-half by simply regulating the diet. Consequently the diet list should be carefully prepared and placed in the hands of those who have charge of the patient. It should be simple, easily digested, and should exclude all coarse, highly seasoned and rich foods, coarse fruits or fried meats, and coarse or fried vegetables.

At the start, if the case is not a favorable one, milk and eggs should be the chief constituents of diet.

Dandruff.

The following combination is recommended by the *Journal of Medicine and Sciences* in the treatment of dandruff:

R. Ammonii chloridii,	5i	41
Tinct. capsici,	5iv	15
Aque q. s. ad.	5vi	180

M. Sig.: Apply to the scalp night and morning with vigorous friction.

Bronchial Asthma.

The same periodical recommends the following combination in the treatment of bronchial asthma:

R. Ammonii iodidi,	5iiss	61
Extracti griseelinæ robustæ, M.	5vi	25
Tinct. lobelie,	5iii	12
Tinct. belladonnæ,	5iiss	10
Extracti glycyrrhizæ, M.	5ii	60
Syrupi toluani, q. s. ad.	5iv	120

M. Sig.: One teaspoonful in water three or four times a day.

Epistaxis.

In severe epistaxis the same periodical recommends that a plug be dipped in Monsell's solution of iron, inserted into the nostril, and so turned as to touch the different portions of the mucous membrane, and a pledget allowed to remain in the nares. If this does not check the bleeding another piece of gauze should be inserted beside the first. They should be allowed to remain until coagulation has taken place; the following day the plug may be removed.

Carnot recommends gelatin as a valuable agent in checking epistaxis. Five parts of gelatin should be dissolved in 95 parts of sterilized normal salt solution, and applied locally by injecting it into the nostril, and then smearing it on cotton or gauze and introducing that into the nares. The solution, when used, should be at about the body temperature. It may be used in the checking of hemorrhage from surface wounds or varicose veins, but is not reliable in hemorrhage from the stomach, because it undergoes digestion; it may be injected when sterilized into the uterus to check uterine hemorrhage. Shurley, in his "Diseases of Nose and Throat," suggests in persistent epistaxis that Veeder's method be employed. This consists in introducing a tampon consisting of a thin rubber bag and filling it with air or water. Another plan is to push well into the nasal passage a fold of glycerin paper or oiled silk in the shape of a glove finger and when it is *in situ*, to fill it with bits of gauze or cotton until the nasal passage is completely packed. A long strip of cheesecloth previously soaked in a solution of hydrogen peroxid can be folded and pushed into the cavity by a probe. Tampons should always be employed in severe cases of epistaxis. The only objection to such treatment is the possible danger of setting up an inflammation with, perhaps, destruction of the mucosa, which, in case of posterior plugs, may lead to disease of the middle ear through the Eustachian tube or to inflammation of the lining membrane of the accessory cavities of the nose.

Medicolegal

Coloring Milk with Annatto.

The Supreme Court of Missouri says, in the case of the City of St. Louis vs. Polinsky, that it is within the common knowledge that the quality of milk depends largely on the nature of the food that cows are fed on; that cows fed on grass, clover or other fresh green food give a quality of milk superior in richness and appearance to that drawn from cows fed on refuse, or winter foods. By adding annatto to the white milk or cream given by winter-fed or poorly-fed cows, a deception is practiced on the milk-consuming public by making this milk of inferior quality assume the rich and golden appearance of superior milk. Such conduct is a fraud and deception on the public and an unfair advantage over honest competitors who refuse to resort to such deception. And the court holds that it is competent for the legislature or municipal assembly to prohibit the use of artificial colorings, such as annatto, calculated to deceive. Indeed, it says that on this point there seems to be much unanimity in the deliverances of the courts of last resort.

Meaning of Word "Body"—Physicians as Witnesses.

The Supreme Court of Illinois says that, in *Elgin, Aurora & Southern Traction Co. vs. Wilson*, a personal injury case brought by the latter party, it being alleged that divers bones of the plaintiff's body had been broken, and the proof showing a fracture of the tibia of the left leg and an injury to the right elbow, it was argued that there was a clear distinction between the body and the limbs of the body, and that consequently there was a variance between the allegations and the proof. But one definition given by Mr. Webster of the word "body" is "the entire physical part of a man." This meaning was properly to be given the word as employed in the allegations. It was not essential that there should be greater particularization as to the bones that were broken.

A physician or a surgeon who has treated a patient, the court further says, may express an opinion as to the physical condition of such patient, based on information gained while so administering professionally for the affliction, or a physician may testify as an expert from information obtained from a physical examination of the person who is the subject of the inquiry. If the opinion of a physician is desired on the case made or claimed to be made by the testimony produced on the hearing, he should not be permitted to state his opinion based on the conclusion arrived at by himself as to the case made

by the evidence as he heard it and gave it weight. The proper course is to state hypothetically the case which the party producing the witness thinks has been proved, and to ask an opinion based on such hypothetical case. The jury, who are the judges as to what has been proven, may then apply the opinion of the expert, if, in their judgment, the state of the case on which it was based has been proven. To permit the expert to base an opinion on the testimony as he construes it and has weighed it would be to permit him to exercise the functions of the jury and, in a sense, decide the whole issues for them.

Constitutionality and Application of Practice Act.

The Constitution of the State of Washington provides that "no act shall ever be revised or amended by mere reference to its title, but the act revised or section amended shall be set forth at full length." In the case of *State vs. Lawson*, a prosecution for practicing medicine without a license, it was contended that there was no law in the state of Washington authorizing the licensing of persons to practice medicine and surgery; that the act of 1890 was entirely superseded by the amendatory act of 1901. The basis of this contention was that the amendatory act of 1901 did not set forth at full length the sections of the original act which were not amended, as it was claimed the Constitution required. But the Supreme Court of Washington says that, whatever support this contention might and in the earlier decisions of the courts of Louisiana and Indiana, it is no longer considered as sound. And it holds that the unamended sections of the act of 1890 and the three sections as amended by the act of 1901 are in full force and effect and constitute the law on the subject under consideration.

The uncontradicted testimony in this case showed that the defendant practiced medicine as defined by the statute. Did he have a license so to do? The testimony tending to show that he had no such license was the following: (1) The testimony of the secretary of the state board of medical examiners to the effect that he never obtained a license from said board; (2) the testimony of the county clerk of King County to the effect that no license or certified copy of a license was of record in his office, and (3) the testimony of the county auditor of King County to the effect that the defendant's name did not appear as a licensed physician in the records of his office. The defendant contended that, notwithstanding all such testimony, he might have been duly licensed in some other county in the state prior to the passage of the act of 1890, and such license not appear in any of said offices. This, the Supreme Court, which affirms a conviction, says, was, no doubt, true, but the statute makes the records of the clerk's office *prima facie* evidence of the existence or non-existence of a license. The defendant conceded this, but said that the statute declared an arbitrary and illogical rule of evidence, and was, therefore, unconstitutional.

The court's answer is: Where a license issued in any county of a state authorizes the prosecution of a business or the practice of a profession in any part of the state, the difficulty of proving that a given person has no license is very great. This fact has induced many of the states to enact laws imposing on the defendant the burden of proving a license in all prosecutions such as this, and these statutes have been declared constitutional. Wharton's *Crim. Ev.* (9th Ed.), Section 342; *Commonwealth vs. Curran*, 119 Mass., 206. If the state can require the defendant to justify under his license in the absence of any proof whatever, it goes without saying that it can likewise declare what character of proof shall constitute *prima facie* evidence.

May Prohibit Placing of Preservatives in Milk.

The Supreme Court of Missouri says that the real question in the case of the City of St. Louis vs. Schuler was whether it was competent for the legislature or the municipal assembly of the city to prohibit the preservation of milk by placing a preservative therein. It was contended that the provision in question against the use of any preservative in milk was to be distinguished from those cases sustaining the exclusion of anatto and other coloring substances, for the reason that the

use of a preservative does not tend to deceive or mislead purchasers and consumers. But the court thinks that the ground on which the use of preservatives in milk rests is the right of the legislature, or in this case the municipal assembly, to pass all needful and proper ordinances to secure the purity of milk, and to prevent any tampering with milk by absolutely prohibiting the use of artificial preservatives therein. The argument that a preservative stands on a different basis from mere coloring matter which is liable to deceive is more plausible than sound. It is a matter of common knowledge that milk is a necessary food of the sick and of the infirm, of the old and the young, that through the agency of impure milk the germs of many diseases are disseminated, and, even where there is an absence of any deleterious impurity of the germs of specific diseases, adulterated or diluted milk is not wholesome and nutritious.

Again, it was insisted in this case that, because formaldehyde works such a chemical change in the character of milk that it will not sour, and because it is for this reason classed as a preservative, the municipal assembly could not lawfully prohibit its use in milk. But the court states that evidently it cannot be said that the effect of formaldehyde in milk is so well known not to be deleterious that the courts must take judicial cognizance of that fact. That its action is such that it changes the chemical properties of the milk so that it will not sour was established and conceded on the trial, and it was for this reason that it was insisted that, as it preserved the milk from souring, it was claimed to be highly beneficial. The court can not accept this conclusion.

It must be recognized, the court continues, that it was a legislative function in the passage of the ordinance in question for the preservation of health to insist that milk should have neither adulterants or preservatives placed in it, and to inquire as to the effect thereof. The municipal assembly may have investigated and found this very fact, that, when formaldehyde or boracic acid was placed in milk, it would change its chemical properties and prevent it souring and prevent it going the natural processes of oxidation and decomposition, and that thereby the housewife desiring to have the milk sour for culinary purposes, or the physician administering it as food to children and sick persons would be misled in his calculations as to its effect on his patient. But, in addition to this, the municipal assembly might well have reasoned that, while one preservative used in carefully prepared proportions might not be injurious to the health of consumers, it would be exceedingly dangerous to permit the vendors of milk, with little or no scientific knowledge and less scruples, each to select his own so-called preservative and use it without knowledge as to the quantities which were safe. This would open the door to all sorts of dangerous adulterations and to the use of highly injurious processes, and the discovery of such practices might never be made until incalculable injury had occurred. The only safe course, considering the nature of the business, was to prevent absolutely the placing of such preservatives in milk. In so doing the municipal assembly in no manner destroyed or affected the defendant's right of property.

 - 5 *Ectopic Gestation. W. H. Randle, Philadelphia.
 - 6 *Diabetic Purpura. C. H. Lefcowitz, Philadelphia.
3. Etiology, Symptomatology and Treatment of Anal Fissure. —The method of operation employed by Bray is division with incision, at the same time trimming the indurated margin of

the wound, and cauterizing the base. The bowels should be kept confined for three days, and after this time daily movements are secured by laxatives. The ulcer usually heals in about two weeks.

5. **Ectopic Gestation.** Randle believes that in many fatal cases in which death is said to be due to so-called heart disease and other causes, in reality it is due to internal hemorrhage from ectopic gestation. He says that in cases of doubtful diagnosis a small vaginal incision may be made through the posterior vaginal vault, when the escape of free blood will verify the diagnosis. The treatment is invariably surgical. As little of the anesthetic should be used as possible, and stimulation should be withheld until the bleeding point is secured. When the abdominal incision is made no attention should be paid to the enormous quantity of blood that usually rushes forth, but the surgeon should place his hand directly on the ruptured tube and clamp the bleeding parts. After this, vigorous stimulation may be employed. The blood clots should be taken out rapidly and the abdominal cavity flushed with a large quantity of sterile saline solution. A quantity of this fluid may be allowed to remain in the pelvic cavity. Drainage is rarely necessary; in fact, it is detrimental. In all cases in which a hematocoele has formed, a vaginal incision may be made with the evacuation of the clots which lie in large quantities in the pelvic cavity; but the patient should be prepared for the abdominal operation, should it prove necessary, because of the recurrence of hemorrhage.

6. **Diabetic Purpura.** Lefcovich reports the coexistence of purpura and alimentary glycosuria in a boy of 3. The patient was nervous and suffered from enuresis and a stomatitis of moderate severity. After two months' treatment, largely dietetic, the boy apparently made a complete recovery. One year later the patient presented the typical aspect of a true diabetes mellitus, but no symptoms of purpura. After nine months' constant attention, the boy remains comfortably healthy while under a judicious diet. Lefcovich emphasizes the importance of urinary examinations in the infant and child in making a diagnosis and in the study of metabolism.

- 11 *Use of the X-Ray in the Treatment of Certain Diseases of the Skin. F. Wise, New York.
- 12 *Ecarache. A. Bardes, New York.

7. **Immunization in Tuberculosis.**—Von Ruck gives clinical results and observations from administration of his own preparation. Taking cases in the early stages of tuberculosis and phthisis, he shows a recovery in 161 out of 171 patients, or 95.5 per cent. Ten patients left the institution satisfied with the results, or continued the treatment at home. Patients further advanced showed a recovery of two-thirds, or 66.3 per cent., with a 27 per cent. result from those in a critical stage of the disease, a condition which would not be obtainable for the most favorable class of tuberculous patients without immunization.

8. **Cancer of the Stomach.**—Dowd calls attention to the large number of deaths resulting from gastric cancer. The census report for 1900 shows that there were at least 9,000 deaths from cancer of the stomach in the United States during that year; this is 65 per cent. more than from appendicitis, and statistics indicate that it is on the increase. He emphasizes the fact that cancer of the stomach is primarily a surgical disease, and considers the mortality from the operation no greater than that from others that are frequently performed. It is important to make an early diagnosis while there is still a fair prospect of cure. Koehler found that the initial symptoms were loss of appetite and pyrosis; that epigastric discomfort often preceded the vomiting by months, and therefore this symptom, which he considered most important, was not constant. Dowd found it in 73 per cent. of his cases, and it had generally existed about seven months before admission to the hospital. Sometimes it was present after every meal,

at others only at irregular intervals. Pain, though not so characteristic, is also an important symptom. Exploratory operation is valuable in helping to establish the diagnosis. A small incision of one and one-half or two inches between the umbilicus and ensiform cartilage is sufficient for the introduction of the finger.

11. **X-Ray in Certain Skin Diseases.**—Wise summarizes his paper as follows: (1) The X-ray will cure ringworm and favus of the hairy skin more rapidly and reliably than any other method of treatment; the advantages of the method are, that it is painless, harmless when properly used, and thorough, and that it cuts down the expense incurred by the city in the treatment and care of these patients to a very considerable extent. (2) Hypertrichosis should be treated with electrolysis, not with the X-ray. (3) The X-ray gives very satisfactory results in the various forms of cutaneous tuberculosis; in keloid, in keratoses, in infiltrated patches of chronic eczema, lichen planus, pityriasis rubra; in the tubercles, ulcers and tumor masses of mycosis fungoides, psoriasis and sarcoma. (4) X-radiation relieves pruritus, burning, tingling and pain; it decreases the discharge and foul odors of various dermatoses, often causing them to disappear completely. (5) In selected cases, radiotherapy is the ideal agent in the treatment of epithelioma and rodent ulcer.

12. **Ecarache.**—Bardes says that as soon as ecarache begins the patient should be kept quiet, put to bed and placed on a fluid diet, and in other ways treated as one would treat a patient with a high fever. The bowels should be kept open, and a single dose of morphin, he states, may be given to insure rest and comfort. Dry heat or else an ice-bag can be applied to the ear. The former is more acceptable to most patients. Every three hours the ear should be gently irrigated with a hot solution of bichlorid 1 to 5,000, after which a few drops of a 12 per cent. solution of carboglycerin can be instilled. Under no consideration should a person be allowed to suffer pain longer than twenty-four hours. If the pain continues, and the drumhead is inflamed and distended, palliative measures are worse than useless, and any attempt to abort the inflammation by means other than surgical is dangerous, and valuable time is lost in so doing. A bulging drumhead should be treated in the same way as a septic formation in any other place. It should be freely incised, rather than simply punctured or allowed to break.

16. **Occult Hemorrhage in the Stools.**—The conditions in which the tests for occult blood in the feces will be of prognostic and therapeutic value in the course of gastric ulcer are said by Steele to be as follows: First, to determine the length of the various periods of the medical treatment of ulcer. Second, to detect the tendency to bleeding during the course of gastric ulcer and by appropriate medical and surgical measures to anticipate and prevent serious hemorrhage. Third, to determine when the medical treatment may be considered to have failed and surgical treatment is indicated. Fourth, perhaps the test may prove helpful under certain circumstances in detecting the development of a cancer on the floor of an ulcer.

18. **Rupture of Symphysis Pubis.**—In a case reported by Eastman, the patient was operated on by a modification of the method devised by Farabaut for suturing the symphysis after symphysectomy. The operation employed in this particular instance is described as follows:

In order to avoid a possible injury to the vessels and nerves adjacent to the clitoris, a crescent-shaped incision four inches long and following the curve of the pubic arch was made. The subcutaneous fat was dissected away, and the anterior surface of the bodies of the pelvic bones exposed. The ends of the bones were found separated about an inch and a quarter, while the intervening space was filled with a semi-solid substance which was readily removed with the handle of the scalpel. The posterior surface of the bone was not exposed nor was the space of Retzius opened except as the removal of the intervening substance exposed it to view. The articular surfaces of the bones were well scraped. Two holes in either side were now drilled through the bone from a point on the anterior surface one-half inch from the articular surface and emerging on the posterior surface one-fourth inch from the articular surface. Through these apertures heavy silver wires were introduced, the pairs brought together by strong pressure on the trochanters and the wires twisted to remain. Union was perfect in thirty-six days. Catgut has been used by various operators. In view of the strain, iron wire may be preferable.

19. Operations on the Insane.—The observations recorded by Brown were confined to cases of abdominal and pelvic surgery. Of 51 operations for displaced uteri, associated with a repair of the cervix and perineum where indicated, the mental recovery was hastened with three patients by the correction of the pelvic abnormalities. On two of these patients a curettage and a shortening of the round ligaments by Alexander's operation was done. On a third, the peritoneal cavity was entered through an anterior vaginal incision and through this opening the round ligaments were shortened; the torn perineum was also repaired. The mental condition of these three patients was acute mania, chronic melancholia and primary dementia. Brown thinks that the following facts have been established: 1. If the operation when needed has been properly done and the patient not mutilated by an uncalculated-for castration, the mental condition is never aggravated by such a procedure. This he states, has been the experience of Manton, who has been operating for over twenty years, also that of Picqué, whose operations have extended over a period of twelve years, as well as his own experience in the entire range of his surgical work among the insane. 2. There exists among the patients confined in the various insane asylums many who are suffering in a quiet, uncomplaining way from pathologic conditions. They have a right to be given relief irrespective of their mental state. 3. Under the stimulus of the improved somatic state resulting from surgical relief some of the patients show greater mental changes under the moral and therapeutic care than was shown before such relief was given. At times this improved mental state continues to one of recovery.

- 28 Treatment of Tuberculosis in Public Institutions. W. Weston, Long Island Hospital.
- 29 Suppression of Tuberculosis in Dairy Herds. A. Peters.
- 30 Day Sanatorium for Consumptives. Parker Hill, Boston. D. Townsend, Boston.

22. Open-Air Treatment of Bone Tuberculosis.—Bradford cites thirty cases of patients treated successfully at the Wellesley Convalescent Home, showing the condition of these patients ten and twenty years after the cessation of the treatment. He says that the success obtained in these cases should stimulate all efforts in the treatment and control of joint and bone tuberculosis, in which the open-air treatment is by no means the least.

23. Human and Bovine Tuberculosis.—Smith states that in institutions in which children are cared for the source of the milk used should receive careful attention, and that herds belonging to the institution should be free from any traces of tuberculosis. In institutions harboring adults there need be less anxiety on this point, and if all animals of reduced vitality or whose udders are not above suspicion are eliminated, the danger of infection may be regarded as exceedingly small. A careful periodic inspection of dairy herds can not be dispensed with, and such inspection should be made a neces-

sary function of state and local boards of health, or of specially organized bureaus, in order that any advanced cases of tuberculosis may be detected, removed and destroyed. More than this can not be demanded at present in the interest of public health.

24. Segregation of Tuberculous Insane.—Rogers is of the opinion that segregation offers a rational, practicable, and not too expensive remedy for conditions that urgently demand relief. The trustees and superintendent of the Danvers Hospital, impressed by this fact, decided that segregation of the tuberculous is the only available remedy. For three years eight or ten female patients were kept in tents on the lawn during the summer months. They enjoyed the tent life and several made rapid improvement. Encouraged by the result of this experiment, the superintendent recommended that two buildings should be erected of capacity sufficient to accommodate all the tuberculous patients in the hospital. These buildings are now nearly completed. Each building will shelter fifteen patients. They are practically alike, one for women and the other for men. They are about 76 feet long and 21 feet wide. They front the south. Each has a piazza ten feet wide running the whole length of the front of the building. The front is nearly all glass, and there is considerable glass in other portions of the walls. The windows are double, and above each window is a glass transom, and all can be raised or swung. The buildings are heated by steam pipes running beneath the windows on three sides of the wards. Fresh air is taken directly through the walls. A sheet iron arrangement causes the air to flow over the steam pipes before it enters the wards. Each building has two wards, 30 feet by 20 feet, 13 feet high, with a room between them 16 feet by 20 feet, containing a fireplace. There is a bathroom and a dressing-room which can be kept warm at all times. The walls are lathed and plastered and painted with lead and finished with a coat of enamel. The floor is covered with linoleum of the best quality. There are openings for ventilation in the ceilings and gable ends. The wards are lighted by electric light. There are no window guards.

- 34½ *An Improved Urethrotome. W. E. Washburn, Kewanee, Ill.

34½. An Improved Urethrotome.—The instrument devised by Washburn in the main resembles the usual urethrotome. The distinguishing feature of the instrument is a cutting knife which is guided by a filiform bougie. The knife protrudes from the end instead of from the side, as in other instruments, and is protected so that it only cuts when and where desired. The bougie is first introduced through the stricture or strictures down into the bladder. The knife is then put in position in the instrument by passing the notched end uppermost through the groove until it is enclosed in the end of the instrument. This knife is held in place by a set-screw. The knife and instrument, when ready for use, are threaded and the instrument is passed into the urethra up to the stricture. The urethra is then dilated, and with the thumb-screw on the side of the instrument, the knife is turned out of the end of the instrument down to the stricture. After the stricture has been cut, the knife is withdrawn in the same way, and the dilated instrument is closed. Other strictures, if present, are cut in the same manner. The knife cuts through the center of the stricture both anteriorly and posteriorly, thus lessening the liability of a contraction result. The knife working in front of the instrument is said to make a clean cut instead of a laceration, thereby rendering infection less liable and healing more prompt. Washburn says that the instrument does not cause any irritation of the urethra.

- 38 Comparative Study of the Systematic Action of Potassium Sulphocyanid. E. Lodholz, Philadelphia.
 39 Suggestions for Preventive Medicine in the Country. A. C. Abbott, Philadelphia.

36. **Tuberculous Peritonitis.** Cummins reviewed 3,405 autopsy records of four hospitals. Of these 835 cases, or 24.5 per cent., presented some type of tuberculosis. In addition 76 records showed healed tuberculous foci. Tuberculous infection of the peritoneum was found in 92 cases, or in 2.7 per cent. of the total, and in 11 per cent. of the cases of tuberculosis. Males were more frequently affected than females, in the proportion of 2 to 1. The disease was most prevalent between the ages of 20 and 10 years, and these cases represent over 40 per cent. of the total. Cummins says that after the fiftieth year the disease is comparatively rare in the female, cases are rather more frequent in the negro than in the white race. The most frequent complication is tuberculosis of the lung. Among women genital tuberculosis is responsible for 40 per cent. of the cases. Among men only a small percentage show some lesion of the genitourinary tract. The other serous surfaces are frequently involved, but instances of true serositis number about 5 per cent. of the peritoneal cases. In laparotomies the fibrous form of the disease gives the greatest percentage of cures, and the ulcerous the smallest percentage. The average mortality is about 3 per cent. Not a few cases undergo spontaneous cure, but the ulcerous form is incapable of such restitution.

Therapeutic Gazette, Detroit, Mich.

December 15.

- 40 Treatment of Shock, with Special Reference to Strychnin. W. W. Keen, E. E. Montgomery, E. Martin, J. C. Du Costa, W. L. Rodman and E. LaFrance, Philadelphia.
 41 Management of Cases of Diabetes Mellitus. J. Tyson, Philadelphia.
 42 Treatment of Insanity with Special Reference to Extramural Cases. F. X. Dercum, Philadelphia.
 43 Certain Stages of Vascular Spasm and Fibrosis. H. A. Hare, Philadelphia.

40. **Treatment of Shock.**—Keen has practically given up the use of strychnin and has substituted adrenalin for it. Montgomery does not believe strychnin to be the best drug for continued use. He says that after the preliminary dose of strychnin better results can be secured from the administration of some preparation of aseptic ergot. Next to intravenous injection of salt solution he has learned to rely on ergot as the most effective agent in shock. Martin says that the only drug which seems to have a distinct action in desperate cases is adrenalin chlorid. This, to be effective, must be given intravenously in extreme dilution (1 to 20,000 normal salt solution) and allowed to flow slowly into a vein. It is transitory in its effects, however, and the injection may have to be repeated. This may be done for from twelve to twenty-four hours through a cannula left in the vein.

Du Costa favors adrenalin administered intravenously with salt solution, and given very slowly and gradually for a considerable time. Rodman says that in mild cases due to anesthesia and the operation combined nothing more is required than oxygen, a decided lowering of the head, and artificial heat. In cases of moderate severity, in which the temperature is from one to two degrees below normal, but unaccompanied with great cardiac and respiratory involvement, enemata of hot coffee and whisky or enteroclysis of hot saline solution, in addition to position and artificial heat, will be all that is necessary. If in addition to a cold, clammy skin, and temperature 96 F. or below, there is much pain, a hypodermic of 1/6 grain of morphin with 1/50 of atropin is added to the above. Hypodermiclysis may be substituted for or used in conjunction with enteroclysis. If the pulse is short, frequent and jerky, above 120, and of poor volume, intravenous infusion, preferably with adrenalin chlorid, is called for; one-half pint to a pint, frequently given, is better than three or more pints at once. LaFrance thinks that strychnin as a cardiac tonic is of almost no value, but that it fails in its purpose if the circulation be at the time too weak to have it produce a stimulating effect on the brain. It is, however, the best agent for reducing shock to a minimum during an operative procedure.

41. **Vascular Spasm and Fibrosis.** Hare emphasizes the following points:—In cases of high tension due to fibrosis the nitrites can be of but little value, and the iodids, with rest and

massage, are needful. Cases of very high tension are usually those in which the heart escapes sufficiently to help maintain the tension. As fibrosis in the peripheral vessels increases, the muscles of the larger vessels undergo hypertrophy, as does that of the heart. It is quite as possible for vascular compensatory hypertrophy to rupture as for the cardiac compensatory hypertrophy to do so. This rupture of vascular hypertrophy often gives the heart a rest and permits it to recover from its fatigue, and so life is saved. It is possible, if the peripheral fibrosis is arrested, for the vessels also to regain power and for a general improvement to ensue. The cardiac stimulants are not needed in these cases as much as rest and the skillful use of alteratives and vascular sedatives.

 42 New Method for Generating Formaldehyd Gas. E. P. Schoch, Whooing Touch, J. R. Landers, Bernadotte, Ill.
 43 Tetanus. W. N. Watt, Austin.

42. **New Method for Generating Formaldehyd Gas.**—Schoch claims for his method that it has the advantages of not requiring any special form of apparatus, of cheapness and freedom from danger of fire. The following substances are required: Good quicklime in lumps, commercial sulphuric acid, and ordinary 40 per cent. formaldehyd solution. A shallow vessel of earthenware or metal is all the apparatus necessary. Sulphuric acid may be purchased at any drug store for 10 cents a pound, and 40 per cent. formaldehyd solution for from 40 to 50 cents per pound. For every 1,000 cubic feet of space are required one pound of formaldehyd solution, one-half pound of sulphuric acid, and three pounds of quicklime. It has been found that just half of these quantities are enough for 1,000 cubic feet, but to guard against excessive loss by leaks these quantities are recommended. The acid and the formaldehyd are first mixed in an earthenware vessel by pouring the acid into the formaldehyd. Then the lime is placed in the shallow vessel in the center of the room. All openings to the room are carefully closed, the mixture is poured on the quicklime, and the operator leaves the room. The rooms should remain closed for from five to eight hours.

50.—See abstract in THE JOURNAL, Oct. 28, 1905, page 1352.

53. **Radical Cure of Bartholinitis.**—When occlusion of the duct results with marked distension of the gland, interfering seriously with locomotion and causing such discomfort as to demand immediate relief, Gallant exposes the inner surface of the labium minus and injects into the mucous membrane over the most prominent portion from five to ten minims of a 4 per cent. cocaine solution, or places a pledget of cotton, saturated with a 10 per cent. cocaine solution between the labia until anesthesia is complete. With a pair of plain thumb-forceps, traction is made on the most prominent portion of the gland (taking care not to rupture it), on the inner surface, and with scissors curved on the flat an ellipse of tissue is cut out, including mucous membrane and gland wall, to the extent of one-third of the sac. When the gland is markedly distended and the sac wall thinned, the first cut will usually bring away enough of the sac, but in some instances the sac contracts so closely that it is necessary to cut away, in circular fashion, more of the wall. Occasionally, when the gland has not been markedly distended, bleeding may necessitate the application of catgut ligatures at one or two points. Immediately following the first cut of the scissors, the contents gush out, and the sac contracts, the swelling diminishes to one-third, leaving an irregular circular opening, the base of which is formed by the remnant of the sac wall. This presents an important

point so frequently overlooked when incising for evacuation of abscesses, viz., that with linear incisions the cut edges fall together in close apposition and readily unite, sealing the cavity; whereas elliptical or circular incisions can not assume a position favorable to such coaptation and, therefore, remain open and drain the cavity, and healing must take place from the bottom. When a true abscess is present, the remaining sac wall will be cast off by granulation; but when the condition is that of a retention cyst, the edges of the sac wall and mucous membrane will unite to fill in the gap made by the excised mucous membrane. The only dressing used has been a pad of sterile absorbent gauze, on which has been poured a small quantity of a mixture consisting of balsam of Peru, 5 per cent., and oleum ricinis, 95 per cent., placed between the labia, to be changed and replaced by the patient each time she urinates. No packing or sutures are required, and the patient can at once walk with freedom from suffering, and with little interference with the ordinary gait. The healing is complete within from seven to ten days.

54. **Local Effects of Peritoneal Drainage.**—Yates concludes that drainage of the general peritoneal cavity is physically and physiologically impossible. The relative encapsulation of the drain is immediate. The absolute encapsulation occurs early (less than 6 hours in dogs), and can be retarded, but not prevented. The serous external discharge is an exudate due to the irritation of contiguous peritoneum by the drain. There is a similar inward current from the potential into the general cavity. This external exudate diminishes remarkably with the formation of encapsulating adhesions. These adhesions, under approximately normal conditions, form about any foreign body. Their extent and density depend on the degree and the duration of the irritation of this body. Primarily fibrinous, these adhesions become organized in a few days (three days in dogs). If the irritation persists, they become progressively more mature fibrous tissue. After irritation ceases, their disappearance depends principally on a mechanical factor—the ability of the involved surfaces to pull themselves or to be pulled loose. Drains should be the least irritating, and should be gradually and finally removed as soon as possible. Irrigation through drains is futile to prevent adhesions and dangerous. After a drain is inserted, all intra-abdominal movements should be reduced to a minimum. As soon as the drain is removed, intra-abdominal activity should be stimulated to aid in the disappearance of the remaining adhesions. Peritonitis, if not too severe, possibly aids in the rapidity of the encapsulation of the drain. A drain in the presence of infection is deleterious to peritoneal resistance, and should only be introduced to exclude more malign influences. Pastoral methods, unless destined to facilitate encapsulation, are both futile and harmful, as far as drainage is concerned. Peritoneal drainage must be local, and unless there is something to be gained by rendering an area extraperitoneal, or by making from such an area a safe path of least resistance leading outside the body, there is, aside from hemostasis, no justification for its use.

55.—See abstract in THE JOURNAL, Jan. 14, 1905, page 152.

58. **Retrodisplacements of Uterus.**—Bovee has histories of 61 patients operated on by the vaginal route, and 68 by the abdominal, or both combined, making a total of 129 cases, with no mortality. This does not include cases in which retrodis-

placement was a feature of the conditions present and in which some other surgical procedure followed. By the vaginal route the round ligaments alone were shortened 21 times, the uterosacral alone 16 times, and both in 21 cases. Various other operations were done at the same sittings; curettage was done in every case; trachelorrhaphy was done 21 times; perineorrhaphy, 23 times; colporrhaphy, anterior or posterior, or both, 14 times, and in 10 cases adhesions to the uterus or appendages, or both, were separated, and ovaries and tubes resected or removed; in one, inguinal herniotomy was done, and in another 2 rectovaginal fistule were closed; in 12, transplantation or lengthening of the anterior vaginal wall, including the uterovesical ligaments, was done. In the 68 patients operated on by the abdominal route, curettage was done 62 times; trachelorrhaphy, 12; perineorrhaphy, 16; colporrhaphy, 10; removal of one or both appendages, 51; herniotomy, 6; appendectomy, 29. Polycic adhesions were separated and diastasis of the recti abdominales relieved 6 times. The round ligaments were shortened by the Budy method in 60 patients, and the uterosacral in 52. Bovee concludes that the complications, rather than the uterine displacement, furnish the cause for surgical relief. All operations done, having in view the correction of uterine displacements, should be based on the pathologic and anatomic abnormalities of the uterus and adjacent structures. Any operation that changes one dislocation of the uterus into another is illogical, and hence unsurgical. As a rule, the largest proportion of cases of retroversion of the uterus that require special operations are best treated by proper procedures on the round and uterosacral ligaments.

59. **Hyperalgetic Zones in Gunshot Wounds of the Head.**—Riebel shows that the areas of hyperalgesia observed in gunshot wounds of the head are identical with those observed by Head: (a) By showing segmental arrangement; (b) by not corresponding with peripheral nerves or posterior root areas; (c) tactile and temperature sense are normal; (d) decreasing intensity. Injury of the peripheral sympathetic (intracranial), either at the base of the brain or in the membranes, can not at present be considered causative of the hyperalgesia. Removal of the Gasserian ganglion (intracranial) or evulsion of branches of the ganglion (extracranial) are not associated with hyperalgesia. Injuries of the dura in other than gunshot lesions do not present referred pain. Besides, fractures of the lighter type with recovery (when injury to the sympathetic might be expected) so far have not shown hyperalgetic zones. The frontal lobes were affected in all cases observed by Riebel. Injuries of the frontal lobes not due to gunshot wounds have not been associated with hyperalgesia. The phenomenon has been observed in gunshot wounds only (in traumatic cases).

61. **Antiseptic Action of Bromin.**—Stroud sets forth the value of bromin as an antiseptic of the highest order. His mode of use is as follows: Bromin 2 drams, bromid of potash 2 drams, and one pint of water are mixed and kept in glass-stoppered bottles. The part to be treated is cleaned as well as possible and wrapped in a single thickness of plain gauze, and over this is applied a thick layer of absorbent cotton. Into a glass jar he puts from 6 to 20 gauze sponges of ordinary size, and pours over these as much bromin solution as they will take up, squeezing out the excess. The glass should be very closely covered, as the fumes of the bromin are very irritating. With a pair of forceps he quickly lays these pledgets on the part, and instantly covers with a thick layer of cotton, and also instantly winds the whole part up in oiled silk, and bandages it very loosely. The result is that the fumes of the bromin, but not the solution, are brought in direct and constant contact with the diseased part. This dressing may be renewed in from 6 to 24 hours. In very severe cases of infection Stroud injects a few drops of the solution, but ordinarily reduces it 1 to 10 with water, and uses this solution to syringe pus cavities and gangrenous patches.

69. **Metrorrhagia Myopathica.**—According to Anspach, metrorrhagia myopathica stands for a distinct class of cases, which have heretofore been variously and incorrectly grouped under apoplexia uteri, endometritis senilis and premenstric bleeding. Metrorrhagia myopathica is a symptom immediately dependent on an anatomic or a physiologic lesion of the uterine muscle. No anatomic lesion has as yet been demonstrated, but it will probably be found in the elastic tissue constituents of the vessel walls and the subserous and supravascular layers. The physiologic lesion is most likely an insufficient contractile power of the uterus. It is possible that the condition is purely functional and that there is no anatomic change which can be recognized. In cases of metrorrhagia myopathica the uterus is enlarged and softened; the os is patulous. Metrorrhagia myopathica does not occur in nulliparous women and, therefore, it must have some connection with the child-bearing process. Anspach claims that the diagnosis of metrorrhagia myopathica is only justified when all other possible causes for uterine hemorrhage have been excluded. This can not be too strongly urged, especially in reference to carcinoma. The terms apoplexia uteri, senile endometritis, and premenstric bleeding as applied to these cases are incorrect and unscientific. While curettement, amniocentesis, etc., has little effect in cases of metrorrhagia myopathica, palliative measures should always be tried before adopting hysterectomy. Obliteration of the endometrial cavity by means of destructive amniocentesis is the alternative of hysterectomy in these cases. Anspach says that it is harder to perform correctly and more dangerous than hysterectomy, which is the operation of choice.

70. **Malignancy of Ovarian Tumors.**—Norris discusses the complications occurring in 63 cases of ovarian tumors. Simple retention cysts, even when of moderate size, are not included in this list. As regards malignancy, he concludes as follows: One in from four to six cases of tumor of the ovaries is malignant, and that this proportion is sufficient to warrant the treatment of all cases of ovarian tumors as malignant until proved otherwise. The operative mortality in cases of malignant disease of the ovaries should not be above 10 or 12 per cent. The number of cures at the end of five years will be relatively small. Carcinoma is by far the most frequent and most dangerous of the malignant diseases of the ovaries, and the recurrence will be largely due to this condition. Every patient with ovarian tumor should be operated on at once, unless there is some strong contraindication. In the so-called "border-line cases" the patients should be operated on because the case may present all the clinical evidences of malignancy, and on operation may prove benign, or the gross specimen may even, together with the clinical symptoms, appear malignant, and on histologic examination prove benign; this is especially true of the adenopapilloma, which frequently, grossly and clinically, closely resemble adenocarcinomatous papilloma. An exploratory laparotomy and the removal of ascitic fluid will make many patients more comfortable, and should certainly be performed when there is any doubt whatever as to the absolute diagnosis of malignancy. All ovarian tumors should be subjected to a rigid microscopic examination, and in cases in which there is any doubt as to the character of the tumor a large number of sections should be taken; and this routine probably, in part, accounts for the high percentage of malignancy occurring in the series of ovarian tumors reported. Norris claims that parovarian cysts

are far less dangerous than true ovarian cysts. In this series of 19 consecutive cases of parovarian cysts there were no complications and no malignant degeneration. Torsion, next to malignancy, he states, is the most frequent and dangerous complication occurring in ovarian tumors, and it occurs in a mild form more often than is generally supposed. In the 63 cases which have been reported, 33.33 per cent. of the patients would surely have died within a short time without operation. The operative mortality for all ovarian cysts should be under 8 or 10 per cent. In the above series it was 3.17 per cent. The operative mortality for benign cyst will be much less. In Norris' series it was less than 2 per cent. The operative mortality for malignant tumors of the ovary should certainly be under 10 or 15 per cent, and early diagnosis and immediate operation on all new growths of the ovary will greatly reduce this proportion.

5. **Mechanism of Condylytomy.**—By means of taking a series of skiagrams in a case of knock-knee requiring operation (Reeves' operation) on both knees, Stevenson found that the alterations brought about for the operation are as follows: 1. The inferior epiphysis of the femur retains its relation to the resected portion of the diaphysis, and the two together may be described as the lower fragment in a complete fracture. 2. The lower fragment is dislocated inward, causing the diaphysis to project outward beyond the external condyle. 3. The lower fragment is also rotated upward and inward round an antero-posterior axis passing through the epiphyseal line in the neighborhood of the intercondylic notch. This displacement is more clearly understood if one considers the direction of the forces applied in straightening the limb. The above rotation or tilting up of the lower fragment has the following consequences: (a) The separation of the epiphysis from the diaphysis externally; (b) the impaction of the compact tissue of the lower end of the upper fragment into the cancellous tissue of the resected portion of the diaphysis in the lower fragment (c) the assumption of a more vertical position of the internal portion of the epiphyseal line. 4. The relations of the tibia to the condyles of the femur are not materially altered. 5. The relation of the epiphyseal line. 4. The relations of the tibia to the latter is not fractured through, although the osteotome penetrates the inferior epiphysis of the femur near the intercondylic notch.

7-12. **Sanatorium Treatment of Consumption.**—Powell has no doubt of the therapeutic value of the treatment of consumption on sanatorium lines which need not necessarily be carried out in sanatoriums. He says that the employment of sanatoriums in the treatment of phthisis is essential in the great majority of cases for the reason that few people, even among the well-to-do, can command those conditions of locality, facilities, space, help and medical supervision which are the important elements of the treatment. He is convinced that there is an unfortunate and exaggerated belief in the person to person infectiousness of phthisis which has grown under the advocacy of sanitarian and antituberculosis societies.

Broadbent believes in sanatorium treatment. He says that sanatoriums serve two distinct purposes—the arrest of the disease in early cases and the prevention of its spread by advanced cases.

According to Williams, sanatoriums are intended for cases of consumption of recent origin, with limited lesions and with little or no fever. They are not places where severe cases should be segregated. Hospitals should be provided for such cases, as is done in Sweden and Denmark. For the treatment of consumption three institutions are required: 1. A consumption hospital to deal with acute and advanced cases; 2. a sanatorium for patients with incipient and limited lesions, and who are for the most part able to take exercise, and, 3. a settlement or colony for patients with arrested consumption where they can be employed on work adapted to their strength and capabilities.

Fowler says that experience has demonstrated the therapeutic value of sanatorium treatment, and that the results obtained may be equally successful with well-to-do patients and with the working classes.

Wethered also is convinced of the therapeutic value of sanatorium treatment, provided that certain conditions have been fulfilled. In the absence of these the results are not so good. The chief of these conditions are three in number: 1. If the disease is in the incipient stage and not acute when the patient first comes under treatment; 2, if the patient remains under active treatment for a sufficiently long period, which, in most cases, should be at least six months; and, 3, if a healthy outdoor life can be followed subsequently. Although sanatorium treatment of pulmonary tuberculosis is the best that has been introduced, it is by no means a specific, and only a certain proportion of the patients show partial or complete recovery. Further, the more independent the patient as regards the necessity of earning a living the better is the result likely to be.

Latham thinks that sanatoriums are essential to the treatment of tuberculosis and that, if properly used as an important part of a co-ordinated system, they are invaluable to a campaign directed toward the eradication of tuberculosis.

16. **Operation for Vertigo.** Lake's patient, a woman, had been deaf in both ears for some time. Both ears had been operated on several times for the cure of suppurative otitis with an eventually successful result on the right side. For four years she suffered very severely with bilateral oral vertigo. The patient was operated on in the following manner: After exposing the bony semicircular canal its upper surface was cut away with the electric burr until the membranous canal was opened. This canal was then followed up anteriorly and posteriorly to the entrance into the vestibule. Then, by means of a small chisel, these two openings were connected by cutting away the intervening bone. Having once obtained a wide entry into the vestibule the whole of its upper surface, or the vestibular roof, was rapidly removed in such a way as to expose the entrance to the posterior ampullary dilatation. All the exposed parts of the vestibule and ampullae were carefully curetted with a fine curette. Thorough drainage was afforded to the small bone-locked cavity by removing the foot-plate of the stapes. This completed the operation, the facial nerve, sheathed in bone, lying between the openings into the vestibule. At the end of three weeks the patient was able to

2000. fairly straight, to go up and down stairs, and to perform all the usual house-chore without any inconvenience.

18. Grafting or Uniting the Testicles. The indications for this operation are multiple, according to Mandlaire. In case of ectopic testicle, synorchidism fastens the testicle in its place and insures better conditions for nourishment. It renders the same service in varicocele and banishes the pain. In case of resection of the vas deferens, intertesticular anastomosis or synorchidism re-establishes an outlet for the sperma by way of the intact organ. The operation is contraindicated after epididymectomy for a progressing bacillary affection, but may be useful after the lesions have long healed. In case of obstruction to the outflow of sperma from a gonorrheal nodule in the tail of the epididymis, synorchidism might prove useful to supplement the implantation of the vas deferens in the head of the epididymis or in the testicle. This aids in re-establishing an outlet for the sperma, and proved successful in a personal case, the details of which are related. Mandlaire has also been successful with the synorchidism in a case of multiple and recurring cysts in the epididymis. All these various methods of anastomosis and grafting may prove useful in the delicate and complex treatment of sterility in males. He has had considerable experimental and clinical experience with the various operations. The preferred method is to freshen the inner surfaces of the testicles with two small crescent-shaped raw surfaces on each and to suture the lozenge-shaped wounds in each testicle to the corresponding wound in its mate. The tunica vaginalis is then sutured around them in such a way as to have but a single tunica for the two. This is his typical operation. The description is illustrated. The ultimate results in his cases have been eminently satisfactory.

26. Disinfection of Books.—Josias discusses the danger of transmission of infectious diseases by the school books used by success-size classes. He also reviews the various methods of disinfection that have been proposed, concluding that all theories need improving. For a small number of books he recommends the Miquel technique. The disinfectant used is a combination of two parts of formaldehyde to one part of sodium chlorid. A strip of cloth is wound on a roller and placed in a vessel containing the disinfectant. The cloth is then wound from the first on a second roller, every part of the cloth being thoroughly impregnated with the fluid. The cloth is then stretched horizontally in the box in which the disinfection is to be done, the cloth having been fitted to the size of the box beforehand. A box of one-half or three-fourths of a meter is the usual size. In twenty-four hours all the contents of the air-tight box are thoroughly sterilized by the action of the disinfectant evaporating from the cloth. This can be readily sterilize books placed on a grating above, and the covers, while the books are not injured in the process, must have access to every leaf.

29. Fresh for Regeneration of Vitiated Air. Gréhant states that a dog breathing into a bag showed that

the air exhaled was deprived of the carbon dioxide by passing the exhaled air through a tank containing 450 gm. of pure, dry potash. The bag into which the animal breathed contained about 300 liters of air. At the end of twelve hours not a trace of carbon dioxide could be detected in the air. The potash was arranged in small pieces on wire netting-trays to insure as large a surface for absorption as possible. The tank grew hot during the experiences, but the potash finally became saturated and ceased to absorb the gas further. When the potash in the tank was dissolved with boiling water later about 71 liters of carbonic acid were derived from the alkaline fluid. Gréhant used in his experiments the Gugliemini-Dräger compressed oxygen and potash apparatus, devised for clinical anesthetics.

29. Action of Iodids on the Circulation.—Pouchet's historical sketch of this subject is supplemented by the conclusions of much personal experimentation and clinical research. He remarks in regard to iodized albuminoids, such as iodized peptone, that they spoil readily and that their use should be under stricter surveillance than at present. Their action on the vascular system declines rapidly in intensity as the preparations grow older, but not their poisonous properties. Their effect on the nutrition and on the nervous system has been injurious in many instances, but the results have generally been ascribed to the affection for which they were being taken. Iodin and the iodids, on one hand, and the extract of the fresh thyroid gland and the iodized albuminoids, on the other hand, have an opposite action on the heart and the extracardiac nervous apparatus. The former induce hypertension, the latter hypotension, in the medicinal dosage. In toxic doses both induce hypotension by their depressing action on the myocardium and by paralysis of the nervous system. The iodids can not be considered heart drugs, in the proper sense of the word, their action on the circulation, in therapeutic dosage, being secondary and subordinate to their action on the lymphatic system and on the blood, as Pouchet relates in detail.

30. Hygiene of Childhood.—More than 154 pages are devoted to the various communications and reports presented to the Académie during the year bearing on the physical protection and hygiene of infants and children. They form an imposing list and testify to immense activity in this line in France on the part of medical men, municipal and state authorities, charitable organizations and private and corporate philanthropy.

- 56 Technique of Examining the Apex.—Examen du sommet du poulmon. M. Letulle.

33. Endemic Index of Malaria.—In the experience of Gros in Algeria, no young children showed any evidence of malaria, while it was frequent among older children. This is because the natives live among the hills, and the young children are not exposed to malaria. When the children are old enough to be sent to tend the flocks in the pasture lands along the rivers they become infected. Examination of the younger children in this region—according to Koch's formula for the endemic index—would indicate that there was no malaria in the country.

34. Deep Injections of Alcohol in Neuralgia.—Ostwalt states that he has made 250 deep injections of alcohol in cases of the dolorous or facial neuralgia, and never has had the slightest mishap or unpleasant by effect. The pain was arrested at once. The effect is like a transient Gasserectomy, as for the time being the functions of the Gasserian ganglion are suspended. In at least 90 per cent. of the cases the neuralgia was cured by the procedure. In about a third of the patients recurrence was observed after four or five months, but one or two more injections definitely banished the pain. He injects 1 or 1.5 c.c. of 80 per cent. alcohol, to which .01 gm. of cocaine or stovain has been added, making the injection along the

trunk of each of the branches affected at the point where they emerge from the bone. He prefers a bayonet-shaped needle and has found these deep injections of alcohol effectual in case of neuralgia elsewhere in the body, in sciatica, etc. He has also cured cases of rebellious facial hemispasm by injecting, a drop at a time, 70 per cent. alcohol along the trunk of the facial nerve, according to Schläffer's technic.

35. Chewing Gum in Treatment of Hyperchlorhydria.—Meunier has been traveling in this country and he informs his countrymen that one in every four American women is chewing gum constantly, and one out of every two men is chewing tobacco or gum. This constant chewing, he was told, is to aid digestion, and he has noticed that the persons chewing presented evidences of hyperchlorhydria. This affection is common among Americans, he adds, as they eat quantities of meat, drink a great deal, and are so devoted to business that they have little time for mastication of their food. On his return home Meunier began to study whether this chewing gum custom was a mere fad or whether it was really beneficial. In hyperchlorhydria the digestion of starch in the stomach is checked by the presence of an excess of hydrochloric acid, and, on the other hand, the presence of the undigested starchy matters induces excessive secretion of the hydrochloric acid. In both of these phases the indications are to help the digestion of the ingested starch, and this is what chewing gum accomplishes. If a person chews gum for an hour and ejects the accumulated saliva into a graduated recipient, from 100 to 150 c.c. of saliva will be found in the vessel. In chewing 100 gm. of bread only from 15 to 20 c.c. of saliva is secreted and swallowed with the bread. Experiments with the Ewald test breakfast confirmed his theoretical reasoning and showed that chewing gum or some similar substance after a meal has a marked influence on the digestion of starch, promoting it by the large supplementary amounts of saliva swallowed, thus eliminating the second phase of hyperchlorhydria. He now orders chewing gum for all his patients of this class.

Semaine Médicale, Paris.

37 (XXV, No. 52.) "Le traitement opératoire des sinusites frontales chroniques." J. Guisez (Paris).

37. Chronic Frontal Sinusitis. The principle which Guisez has adopted in case of chronic frontal sinusitis is that the ethmoidal sinus is always involved in the process. This necessitates thorough evacuation of its contents. He accomplishes this by turning back a flap, made by an incision in the upper third of the eyebrow, extended .5 cm. below the inner angle of the orbit. The flap thus made can be replaced without leaving a trace, while it allows ample access to the sinus. The frontal sinus is trephined. The results have been very satisfactory in 18 cases in which he has operated by this technic. The only drawback is that the nasal fossae become enlarged by it. He overcomes this by injection of paraffin afterward. The skin wound heals in a week or two, but the intranasal healing is a slower process, requiring treatment for a time. Cure is not complete until all traces of exudation, seabs and crusts have vanished.

42. Treatment of Malignant Furuncle on the Face. Rosenbach relates the particulars of 3 cases in which a furuncle on the face had developed into a malignant phlegmon with impending pyemia and sepsis. The *Staphylococcus aureus* was found in pure cultures, but it must have been exceptionally virulent. He is positive that this enhanced virulence is the result of the anatomic conditions of the parts. The muscles of the face are continually forcing and pumping material from the furuncle into the adjoining tissues, causing the spreading of the inflammation and suppuration in lines radiating from the original focus. He was able to trace the development of these cords of suppuration radiating from the furuncle, and interfered by making an incision along each of these radiating cords, as well as in the furuncle itself. The result was the gradual healing of the lesion. One of the 13 illustrations shows a young man with eight of these incisions. The furuncle in all Rosenbach's cases was on the upper lip. One of the incisions encircled the base of the nose, three were on the chin and the rest were on the cheeks near the focus. The incisions allowed the evacuation of pus and necrotic tissue and coeci, or at least of toxic fluids abounding in coeci, and also permitted local treatment with iodoform. The incisions and local treatment seemed to transform the negative into positive chemotaxis. One of his patients presented metastases in the ear, ankle and parotid gland.

46. Peruvian Balsam in Treatment of Wounds.—Schläffer has treated more than 100 cases of wounds with Peruvian balsam and his experience has convinced him that the balsam has certain properties which surpass those of any other substance at our disposal for the treatment of wounds, especially in crushed and soiled tissues. Severe inflammation never develops in any wound treated with the balsam in the first twenty-four hours. The balsam is poured into the wound and every crevice filled. It attracts the leucocytes to the spot and has a kind of mummifying effect on the dead tissues, while it mechanically checks the development of micro-organisms.

49. Operative Treatment of Epileptics.—Friedrich tabulates the particulars of 11 cases of epilepsy of supposed traumatic origin in which an operation was undertaken. Among the lessons learned from this experience is that operative intervention may prove useful when the symptoms of the aura and the objective findings suggest traumatic conditions, even although the beginning of the seizure may not correspond with the point of the supposed trauma according to the accepted topography of the cortex. During the interval also careful search should be made for symptoms suggesting organic trouble, especially headache at a certain point recurring after physical or mental exertion or after emotions or certain pleasures or in sleep. The onset of the seizure should be studied, whether the same groups of muscles are always involved and whether the subsidence of the seizure obeys certain territorial limitations. Some of the 11 patients were remarkably improved and one completely cured, while a number were only transiently benefited.

52. **Tuberculous Peritonitis in Children.**—Faludi sifts the literature on this subject and reviews the material at the Stephanie Hospital, his conclusions being all in favor of laparotomy at the earliest moment in cases of ulcero-carcinoma or fibro-adhesive tuberculous peritonitis in children. The results are liable to be excellent in such cases. In the form with effusion, hygienic-dietetic treatment should first be given a thorough trial. If it fails or is not convenient, then laparotomy should be done without delay. Punctures should not be attempted. A serious tuberculous affection in another organ is a contraindication to laparotomy, but not so fever or debility. Circumscribed tuberculous inflammations in children always demand surgical intervention. The after-treatment in all these cases is of vital importance, the dietetic and hygienic measures being supplemented by the proper anti-tuberculosis medication.

55. **Bladder Stones in Children.**—The tabulated results of Winternitz's operations for bladder stones in children certainly speak in favor of his technic. He crushes the stones and removes them by suction through a tube when the concretions are movable and crushable, the bladder and upper urinary passages free from infection, and the urethra at least as wide as a No. 16 Charnière sound. When the urethra is smaller than this, or when obstinate catarrh of the bladder or posterior urethra resists treatment, then he resorts to the high incision. He examines with the cystoscope to see if any fragments have been left behind after crushing the stones, and on this account does not attempt to crush them when the children are too small to allow the introduction of the cystoscope. He tabulates the details in 28 cases.

56. **Ovarian Tumors in Children.**—Winternitz reports 4 cases cured by operation. The tumor was an embryoma in all but one. Palpation of the tumor usually differentiated the ovarian growth, but appendicitis had been diagnosed in one instance. In this case a dermoid cyst of the ovary, after torsion of the pedicle, had suppurated and perforated through the abdominal wall.

57. **Teratoma of Thyroid Gland.**—Two cases are reported, both cured by operation. They were in infants of 2 and 8 months, respectively. If such a tumor causes no disturbance it might be advisable, he states, to wait until the child is from 1 to 3 years old, but in case symptoms develop earlier prompt interference is required. The total excision of the tumor, as large as a fist, in the left lobe of the thyroid, was borne well by the 8 months' infant. Careful preliminary ligation of the vessels is indispensable. Cartilage tissue was prominent in each of the tumors removed. The tumor in the younger infant originated in the isthmus and was readily removed, the infant being dismissed in good health a week later.

58. **Venesection in Scarlatinal Uremia.**—Singer advocates venesection as the most rational and beneficial measure in scarlatinal uremia. It is especially indicated in cases showing symptoms indicating irritation of the brain. When there is a tendency to coma and depression, venesection can do no harm, but not much can be hoped from it at this stage. It is applicable to both robust and weakly children. If the pulse is filiform, the internal organs are generally irreparably injured at this stage and the operation is generally useless. Venesection should be done as early as possible, during the first uræmic attack. The amount of blood to be withdrawn must be decided by the age, strength and severity of the attack. Venesection can be repeated at need after from twenty-four to forty-eight hours. Baginsky thinks that from one-fifteenth to one-twentieth of the total amount of blood can be let out without danger. In Singer's 17 cases of acute scarlatinal uremia treated by venesection, all the patients recovered but 2, that is, the mortality was 12 per cent. In the 9 cases treated without venesection the mortality was 56 per cent.

64. **Diagnosis of Lung Affections.**—Düniges tabulates the findings in 46 patients with special regard to comparison of the elasticity of the soft parts on both sides of the chest in pulmonary affections. The course of the cases confirmed the finding that the tonicity on the affected side is materially diminished in case of unilateral apical affections. In the bilateral affections, the tonicity is less on the side most involved. Careful symmetrical palpation of both sides of the chest will reveal a difference in the tonicity of the soft parts before any other evidences of a pulmonary affection are evident. It is well to mark a number of points on the skin to insure symmetrical examination. The physician stands behind the patient and palpates especially in the clavicular fossa with his fingers, his thumbs in the infraspinous fossa, pressing on the muscles and comparing the resistance on the two sides. Düniges is confident that systematic palpation to compare the elasticity of the soft parts on each side will reveal many an unsuspected incipient tuberculous affection in the apices.

65. **Orthopedic Treatment of Nervous Affections.**—Haudek reviews the various ways in which orthopedics and physical measures are now summoned to the aid of nervous affections. They have contributed to improve the prognosis to a remarkable extent in many cases of paralysis, etc.

66. **Albin Test for Invisible Blood in Feces or Stomach Contents.**—Extensive tests by von Torday have confirmed the great value of the constant finding of blood in the feces or stomach contents as a sign of cancer. The guinea test is too delicate for general use, but the albin modification can be recommended in high terms, he says, corroborating the similar assertions by others. For the modified albin test, about 5 c.c. of the feces or stomach content to be examined, after removal of the fat, is rubbed up with ether, with a little alcohol if necessary, which is afterward filtered out. About 5 c.c. acetic acid are then rubbed in and 10 g. of ether are mixed with the material and the whole filtered. Then 1.5 c.c. of ozonized turpentine is poured over the extract resulting from the filtering and also .5 c.c. of an alcohol solution of albin. If blood coloring matter be present, a red ring forms at the junction of the turpentine and the whole of the fluid assumes a diffuse red tint. The turpentine may float on the surface or sink to the bottom, the characteristic red ring forms along its edge. Food containing much chlorophyll does not interfere with the test, but large amounts of urobilin in the feces must be extracted with alcohol beforehand. It is important, also before the test, for the patient to refrain from eating meat with red juices and medicines containing iron. This test will reveal "occult" hemorrhages without fail, and when the test is constantly positive some cancerous lesion should be suspected.

71. **Lymphatic System and Tuberculosis Infection.**—Bartel noted in some experiments on rabbits fed with virulent tubercle bacilli that a latency of 104 days was evident in some in-

stances. This fact, in connection with the finding of virulent tubercle bacilli in glands which showed no trace of the characteristic tuberculous process, has convinced him that a tuberculous process passes through a phase of small-celled hyperplasia the same as a pyogenic infectious process. There can be no doubt, he thinks, that the lymphocyte is capable of exerting an inhibiting influence on the tubercle bacillus in respect to its action on the living organism.

72. Typhoid Inflammation of Gall Bladder.—The pus from an empyema of the gall bladder in a woman who had long presented evidences of cholelithiasis revealed typhoid bacilli in large numbers. There was a history of a brief febrile affection a year or so previously which must have been typhoid. Dörr injected various bacteria into a vein in rabbits and found that they penetrated into the gall bladder in the course of eight hours or less. Typhoid, paratyphoid, colon and dysentery bacilli proliferated in the gall bladder and were found flourishing there after four months, long after the bacilli had vanished from the marrow, urine and liver. Intravenous injection of typhoid bacilli was always followed by a suppurative but rapidly healing inflammation of the mucosa of the gall bladder. The proliferation of the typhoid bacilli in the gall bladder did not confer agglutinating power on the blood. The typhoid bacilli in the gall bladder are liable to be eliminated in the feces from time to time. It proved impossible to free the bile from injected germs by any therapeutic measures; even intravenous injection of antiseptics failed to render the bile sterile.

73. Camphor and Atropin Poisoning.—Lühl analyzes 6 cases of severe poisoning from the use of camphor and the same number of cases of belladonna or hyoscyamin poisoning, all terminating in recovery. The atropin or oil of hyoscyamus was taken internally by mistake in 4 instances. In the fifth eczema on a child was treated with a lotion prescribed for the mother's rheumatic pains, followed by symptoms of atropin poisoning on the part of the child. In the sixth case, a physician prescribed atropin suppositories in mistake for belladonna. The woman presented the typical picture of atropin poisoning when seen soon after she had used the suppositories. The atropin in the stomach should be removed by emetics, followed by lavage after an injection of morphin. Purgatives and enemas are also useful in case the poison was taken by the mouth. If injected, the place of injection should be cut into and the blood squeezed out. Potassium permanganate is said to be a chemical antidote to atropin. The lavage can be done with water tinted with the permanganate to a pale bluish pink; the permanganate can be given internally in spoonfuls of a .25 to .5 per cent. solution. Ilseemann recommends administration of tannin, and others iodine and potassium iodid. Morphin is extremely valuable, but it has no action on the heart, and in case of stupor, coma or paralysis it may do actual harm. In such case stimulation of the skin, black coffee, camphor, caffeine, etc., are indicated. The nervousness and insomnia are best combated by tepid baths, and the patient should drink as copiously as possible. A large proportion of the atropin poisonings on record were due to carelessness in prescribing. Very small doses may affect a susceptible person. Féjer's patient presented serious symptoms after the mere installation of a little atropin in the eye. Intoxication has followed even doses of 1 or 2 mg. and .01 gm. has proved fatal to children. In using the scopolamin-morphin method of anesthesia, extreme caution is required to prevent poisoning. In regard to camphor poisoning, Dörr advises lavage of the stomach as less weakening than repeated vomiting. The intestines can be emptied with sulphate of magnesia or of soda or calomel. Castor oil should be avoided, as also alcohol and milk, as these dissolve the camphor. In case of collapse, stimulation of the skin, and opiates for excitement, injection of morphin, chloral by the rectum or sodium bromid. The patient must be kept warm. Jaksch recommends venesection and saline infusion, and Berkholz advises white sugar as an antidote. Possibly the sugar acts by hastening the transformation of the camphor into campho-glycuronic acid.

74. Standard for Normal Feces.—Oefele's pioneer work in the study of the feces requires a normal standard for compar-

ison before the results can be applied to practical use in the clinic. He suggests as a basis for study that the feces of well-to-do persons, such as those who visit the spas and take courses of mineral waters, should be used to get the average of a large number. It might be desirable if a standard test diet could be arranged for the purpose, free from waste material; but, on the whole, it is better, he thinks, to study large numbers of persons rather than a small number on a prearranged diet. Examination of the feces of large numbers of guests at a watering place would produce a composite standard for the average feces, which could be utilized in study of the coprology of well-to-do patients. The expense of such research confines it exclusively to such material. Unless a normal standard is determined in some such way, the study of coprology will be aimless.

79. Experimental Injection of Cholin.—A weak solution of cholin injected directly into the testicles or spleens of small animals caused changes similar to those observed under exposure to radium.

89. Anesthesia for Children.—Guimarães advocates chloroform for long operations and ethyl chlorid for short ones when they are to be performed on children. Spinal anesthesia is good and effectual, but it frightens the children too much.

91. Embalming in Rio.—Da Rocha gives a list of prominent persons who have been embalmed in his city and exposed to public view weeks or months afterward. The list includes the pianist Gottschalk, whose public funeral later at Philadelphia was an ovation to his memory. Only one medical name is in the list.

93. **Ignipuncture of Tuberculous Joints.**—Guimaraes reviews the history of this intervention and describes the excellent results attained in a case of a tuberculous hip-joint affection in his own experience. After ethyl chlorid anesthesia, five times the actual cautery was inserted in the joint down to the bone, and a compressing bandage then applied. About three weeks later chlorid of zinc was injected into the joint, and the injection was repeated a fortnight later. The results were most excellent, both in regard to the prompt healing of the tuberculous lesions and the restoration of function.

100. **Eye Affections in Smallpox.**—Abreu Fialho has observed ocular affections in a large number of cases of smallpox. Both eyes were affected in 16 out of the 65 patients with eye troubles from this cause; total blindness resulted in 4, and in 15 the sight of one eye was completely lost. About 50 of the patients were under 18. Fourteen different kinds of ocular lesions were observed, but the majority were superficial keratitis and keratoiritis with hypopyon. It is important, he says, to open the eyelids by mechanical measures when they are much involved, and to instill an anti-septic or to apply an eye wash of methylene blue in a concentrated solution.

107. **Necessity for Vaccination After Smallpox.**—De la Guardia is chief of the vaccination service in Cuba, and he says that he has had occasion to vaccinate 1,599 persons within a certain period, 328 of whom presented signs of having already had smallpox. Of these 328, 47 had never been vaccinated, and the vaccination resulted positively in 17. The results were also positive in 18 of the 263 who were revaccinated. The results were thus positive in 65 out of 328 persons who had already passed through smallpox, about 20 per cent. of the total.

108. **Mechanical Polyneuritis in Women.**—Vento's patient was a woman of 31, a vi pará—who had suffered from paralysis of arms and legs two years previously, with considerable pain in the muscles. The attack of paralysis lasted about two months, and then the patient gradually recovered the use of her limbs, but the paralysis recurred about a year later and persisted for several weeks. The paralysis of the arms finally yielded to hypodermic use of strychnin, but the legs remained paralyzed. The uterus was in retroversion, with a slight endometritis and laceration. The displacement of the uterus was corrected, after which the paralysis of the legs rapidly subsided and the patient was discharged, quite cured, in less than three weeks. Vento accepts compression of the sacral plexus and its branches by the *retro vertes* uterus as the direct cause of the paralysis of the legs. The compression of these nerves also induced vascular disturbances which interfered with normal circulation in the spinal cord and prevented its proper nourishment, thus secondarily entailing the paralysis of the arms. This assumption of a mechanical polyneuritis was confirmed by the gradual subsidence of all the symptoms under treatment based on it.

112. **Purification of Vaccine.**—De la Guardia relates experiences which sustain the claims made for the method of purifying vaccine by passing air charged with chloroform through it according to the technic of Alan Green.

119. **Rare Form of Pernicious Malaria.**—García's patient was a 9 months' babe whom he found absolutely unconscious and insensible, temperature subnormal, pulse filiform, 130 to the minute, the skin pale and dry, respiration rapid but regular, and no contractures. The attack had come on suddenly with a dry cough; the comatose condition followed in a few minutes. There were no pathologic antecedents in the child or the parents, but the locality (Vera Cruz) suggested the possibility of malarial intoxication, and García made a subcutaneous injection of 1 gm. (15 grains) of quinin hydrochlorid. He always uses this dose in pernicious malaria, irrespective of the age of the patient. He also gave a rectal injection of 2 liters of warm artificial serum and had the child wrapped in hot wet sheets, with cold applications to the head. The drop of blood that escaped when the quinin was injected was almost black. A few minutes after the injection the symptoms began to subside, and in less than four days there was no trace of the child's illness except a small abscess on the left buttock where the quinin had been injected.

120. **Pneumococcus Infection of Genital Apparatus.**—Menocal describes 3 cases in which pneumonia of the lungs was complicated by a pneumococcus vaginitis and thrombophlebitis of both spermatic cords in two patients and by orchio-epididymitis in the third. The patients were men of from 38 to 51 years of age. No pneumococci could be found in the genital lesions, but the pneumococcal origin of the complications, he thinks, is beyond question, for reasons which he enumerates.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

GANGRENE OF THE GALL BLADDER. RUPTURE OF THE COMMON BILE DUCT,

WITH A NEW SIGN.*

JOSEPH RANSOHOFF, M. D., F.R.C.S.
CINCINNATI.

In 1879 I had the privilege of reporting my first gall-stone operation to the American Medical Association. In the intervening years, the surgery of the gall bladder and bile ducts has been so far developed that individual case reports have no place in our overburdened literature, unless, as by their aggregated number, they add weight to some general principle involved in the choice of and time for operation, or throw light on the causes of death in seemingly simple cases. The two case reports, I submit, do not belong to either category, but their comparative rarity must serve as my excuse for presenting them.

GANGRENE OF THE GALL BLADDER.

Patient.—A. B., male, aged 21, was admitted to the Jewish Hospital June 25, 1905.

History.—The patient, whose father and mother are both living, has never, to his knowledge, been ill, except for a pneumonia four years before the onset of the present trouble. Three days before admission he was taken with very violent pain in the lower part of the abdomen. He attributed it to rather free indulgence in beer, which he vomited after ingesting it. Four hours after the beginning of the symptoms the physician who was summoned administered morphia hypodermatically for the relief of the pain, which had become intolerable. Ice bags were ordered and applied continuously. Although the starvation treatment had been rigidly carried out, the vomiting continued at frequent intervals, except when the patient was under the influence of morphia. The diagnosis of appendicitis had been made and operation advised within twenty-four hours of the beginning of the attack. The bowels were moved by enemata.

Condition on Admission.—The patient was well developed and well nourished. Temperature 100 plus; pulse fluctuated between 100 and 120. The patient had a very anxious facial expression and vomited frequently large quantities of bile-tinged fluid. The tongue was dry and heavily coated. The abdomen was very much distended, with marked muscular rigidity on the right side. Percussion showed excessive tympany which had pushed the liver dullness upward. Although the entire right side of the abdomen was tender to the touch, the tenderness seemed most acute in the lower quadrant and in the loin. The blood count showed leucocytosis of 31,600 white.

Diagnosis.—Acute appendicitis, with gangrene probable.

Operation.—An incision was made through the right rectus. When the peritoneum was opened, a considerable quantity of turbid serum escaped. The coils of distended and congested intestine appeared in the wound covered in many places with flakes of whitish lymph. They were held aside with considerable difficulty. The appendix was readily brought

into view and removed. While it presented evidence of inflammation like the adjacent coils of intestine, there were no adhesions and no signs of perforation. It seemed evident that this was not the source of the peritonitis. The incision was, therefore, elongated for better exploration. There was revealed a tensely distended gall bladder almost uniformly black and without any luster. This appearance of the gall bladder could be seen, through the large wound, to extend to the very neck of the viscus. The examination was made easy by the absence of adhesions, either recent or old. Before deciding to open the gall bladder, as is my invariable custom, the common duct was carefully palpated for a stone or other tangible cause of obstruction, but none was found. After carefully protecting the intestine with aprons, the gall bladder was incised and about ten ounces of ropy, viscid bile mixed with blood clots were removed. There was no pus. The vesical contents were free of odor, and a number of cultures on agar-agar and blood serum were made. All remained sterile. Most careful exploration of the gall bladder failed to reveal either stones or biliary sand. The operation was completed as an ordinary cystotomy, except that enough gauze packing was inserted about the gall bladder to protect the general peritoneum from a new infection from the sloughing process which was sure to ensue. After thorough toilet of the abdomen, the lower part of the wound was closed by layer sutures.

Result.—The operation left the patient with a pulse of 150; the recovery, nevertheless, was rather rapid. Vomiting ceased at once. For ten days the temperature fluctuated between 101 and 103, when it and the pulse rate returned gradually to the normal. On the third day after the operation, the dressings were saturated with bile, which did not come through the intra-vesical drainage tube. Five weeks after the operation the gall bladder was discharged almost en masse from the wound. The black slough showed the various coats quite down to the cystic duct. After the expulsion of the gangrenous mass, the biliary fistula healed rapidly. The patient left the hospital September 3. He has since regained full health and weight. The wound is solidly closed.

RUPTURE OF THE COMMON DUCT, WITH AN UNUSUAL SIGN.

For the following history I am indebted to Dr. J. E. Greive:

Patient.—W. B., aged 53, occupation, merchant; residence, city.

Family History.—Father died at the age of 65 from cancer of the stomach. Mother died at the age of 84; cause of death, "old age." One sister died at the age of 48 from cancer of the breast. One brother died in infancy; cause unknown. Four brothers are living; one is now suffering from locomotor ataxia. Another of the brothers, at the age of 6, had an attack of infantile cerebral palsy. Two sisters are living and well.

Personal History.—Patient claims not to have had the ordinary diseases of childhood; in fact, not to have been ill until 6 years previously, when he passed through a moderately severe attack of typhoid fever, from which he made an apparently perfect recovery. In April, 1905, he had what appeared to be a very mild case of acute indigestion, lasting not longer than twelve hours. At that time he had no fever, no vomiting, and considered himself perfectly well on the following day. On Aug. 19, 1905, while on a vacation at Prince Edward Island, he was seized with severe, sharp, colicky pains, which he lo-

* Read before the Southern Surgical and Gynecological Association.

cated in the region of the umbilicus. The pain began at 11 o'clock at night after he had retired and continued to be severe all night; it was partially relieved by an enema on the following morning. He was seen by his physician the next day, who pronounced the attack one of acute indigestion, and ordered a dose of castor oil, which secured a very free movement of the bowels. The pains continued, however, but became less and less intense and disappeared after four or five days, during which time the patient remained on a restricted diet. There was neither fever nor chill during this attack, nor was the patient at any time jaundiced. From that time until the onset of the present trouble, October, 1905, the patient considered himself absolutely well, attending to his business and enjoying perfect health. Even on the morning and afternoon of the day when the trouble began he performed his usual duties about the office. The attack came on suddenly at 6:30 p. m., beginning with a severe chill, which lasted about twenty minutes.

Examination.—I saw the patient half an hour after the chill had subsided. He was resting in bed and seemed fairly comfortable, except for a slight uneasiness, not a severe pain, in the upper right quadrant of the abdomen. Pulse and temperature were normal. There was neither nausea nor vomiting. The bowels had acted freely early in the morning. An examination of the abdomen revealed a tenderness, but very little rigidity, in the right hypochondrium. The region of the ileocecal valve was absolutely free from pain and tenderness. The abdominal walls were very soft and relaxed.

Course of Disease.—The patient was ordered to remain in bed and was given nothing, except a dose of Carlsbad salt early on the following morning. During the night the pains in the right hypochondrium became more severe, and when seen early in the morning there was some slight rigidity of the abdominal wall in this region. The Carlsbad salt had been rejected by the stomach. Pulse was 76; temperature, 99. The region of the ileocecal valve was free from pain and tenderness. During the day he was seen at frequent intervals, and, on account of the severity of the pain, which was sharp and cutting in character and now equally distributed over the whole right side of the abdomen, he was given hypodermic injections of morphia. During the day the pulse and temperature, taken at intervals of every three hours, ranged between 76 and 92, temperature 99.2 to 99.8; the pulse was full and regular. An examination of the thoracic organs revealed heart and lungs in good condition. The urine was high colored and acid; the specific gravity was 1024, and there was a trace of albumin. There was no sugar and only a slight trace of indican. The abdomen became very much distended and decidedly tympanitic; no bowel movement was obtained, in spite of repeated lavage of the colon. The patient suffered excruciating pains, which were now localized very definitely on the right, with the seat of the greatest intensity over the lower right quadrant of the abdomen. There was exquisite tenderness over McBurney's point. Again during the night repeated injections of morphia were given to relieve the pain. All efforts to obtain an evacuation of the bowels during the night and following day were unsuccessful. On Saturday the distension of the abdomen continued; there was extreme tympanitis, pain and tenderness, most marked on the right side, and particularly over McBurney's point. There was no dullness on percussion over this area. After this the patient referred all his pain to the lower right quadrant of the abdomen. The temperature at no time on Saturday rose above 99.2, the pulse varying from 86 to 96. In the evening, at 7 o'clock, lavage of the bowels with warm water, glycerin and Epsom salts produced an evacuation of mucus, which was slightly bile tinged and which had a distinctly fecal odor. After this evacuation of the bowel the patient rested somewhat easier, but on Sunday morning, at 3 o'clock, I was called again to see him. The pains in the right lower quadrant of the abdomen had become very intense, requiring the injection of a half grain of morphia. There was a distinct change in his facial expression, the breathing had become shallow and rapid, the pulse was small, easily compressible and irregular. The abdomen was more distended and very tender on pressure on the right side low down. There was very little tenderness to pressure over the region of the gall bladder. It was evident from the severity of the peritonitis, the extreme distension and

the changes in character of the pulse and respiration that the time for an abdominal section had come. The patient at no time had been jaundiced, and it was left for the operator to determine the nature of the peritoneal inflammation.

Condition on Admission to the Hospital.—Patient was a large-framed man, with every indication of intestinal obstruction from peritonitis. His facial expression was anxious, pulse about 130, temperature 100. Examination of the abdomen revealed extreme tympany, with the liver dullness very much pushed up and reduced in area. On inspection of the abdomen, attention was called to a marked jaundice of the umbilicus. The navel was of a distinct saffron-yellow color in strong contrast with the rest of the skin over the abdomen. It was the only evidence of jaundice. Tenderness was extremely marked over McBurney's point.

Probable Diagnosis.—Peritonitis of appendical origin.

Operation.—Gas-ether anesthesia. An incision was made through the outer border of the right rectus muscle. When the subperitoneal fat was reached, it was found markedly tinged with yellow. With the opening of the peritoneum, there poured forth a quart or more of free bile mixed with serum. The coils of the small intestine were loosely agglutinated and in many places covered with shreds of lymph. It being evident that we had to deal with a rupture of either the gall bladder or of one of the bile ducts, the incision was rapidly elongated. The gall bladder was found quite empty and retracted under the liver. It could readily be traced to the cystic duct, and neither in the latter nor in the gall bladder was there any sign of inflammation beyond the general redness which appeared everywhere on the peritoneal surfaces exposed. The gall bladder did not seem particularly thickened. After thoroughly removing with gauze sponges the free bile in the peritoneal cavity, it was evident that the flow of bile continued from the aperture behind the gastrohepatic ligament. The fat in the great omentum was very deeply stained with bile. By holding the latter aside and pressing the viscera, with gauze aprons to the left, a tear could be felt in the posterior wall of the common duct, through which the bile without question had escaped. The tear admitted the end of the little finger and it was in the supraduodenal part of the common duct. It could not be brought into view. As careful a search as possible was made for a stone, but none was found. The condition of the patient did not warrant unnecessary prolongation of the operation, which was completed by making a stab puncture through the loin and inserting through it a half-inch drainage tube. A second tube was inserted to the anterior surface of the gastrohepatic ligament. About this considerable packing was placed. The flow of the bile from the posterior tube was very free for three or four days, from which time on it gradually became less and ceased altogether in ten days. From this time on the recovery was uneventful.

REMARKS.

Although the cases presented differ in many important points, they have enough factors in common to warrant their consideration together. In the first place, in each of them, a rapidly developing peritonitis made an operation absolutely imperative as an *indicatio vitalis*. In each of the cases the operation revealed a condition which to the naked eye, at least, had all the signs of a peritonitis, which might speedily cause death. In one of the cases there was an unruptured, but gangrenous gall bladder, the contents of which were proved to be sterile; in the other, free bile in large quantities was found in the peritoneum. Unfortunately in this case cultures were not made, but the gall bladder appeared normal. Since the reports of Naunyn,¹ Hayem,² Lane³ and others, which appeared some fifteen years ago, it has become the vogue to look on normal bile as a rather inoffensive agent when thrown into the peritoneum, and experiments in animals have been often made, notably by

1. Naunyn: *Klinik der Cholelithiasis*, 1892.

2. Hayem: *Gaz. des Hôpitaux*, 1889, p. 12. Cited Erhardt.

3. Lane: *London Lancet*, 1891, vol. I.

Erhardt,⁴ to bear out this view. That bile has a tendency to destroy the virulence of the bacteria with which it comes in contact has been fully established, and this doubtless explains the fact that the peritonitis consequent on lesions of the biliary ways is less likely to become rapidly generalized and fatal than is perforation peritonitis from other causes, such as appendicitis. The tendency to the formation of protective adhesions is greater perhaps also because of the natural diaphragm which the colonic arch and the mesentery form between the biliary ways and the general peritoneal cavity below. Abscess formation and even spontaneous recovery, therefore, are not uncommon. It appears even that post-operative results are excellent. Neck⁵ has collected eleven cases of spontaneous rupture of the gall bladder containing stones, with eight recoveries. On the other hand, Korte⁶ has seen nine such patients, of whom five were beyond operative help. Of four patients operated on, two recovered. In the fatal cases, death resulted between the third and tenth days. Moynihan⁷ and Mayo Robson⁸ cite a number of cases in which death resulted from uncomplicated wounds or tears in the biliary ways. It is not safe, therefore, to regard the bile as a too innocuous agent when poured into the free peritoneum. Hahn⁹ has recently collected seven cases of rupture of the ductus choledochus of traumatic origin, in all of which the patients died with one exception. In the case of rupture of the common duct reported, it is more than likely that it resulted from the impaction of a stone. That none was found at the operation does not militate against this theory in view of the previous history of the case. Just when the rupture took place it is impossible to state, but probably not later than thirty-six hours after the onset of the symptoms.

Regarding the diagnosis in the cases presented, it must be regretted that a correct diagnosis was not made of the cause of the existing peritonitis. In the case of gangrene, a diagnosis of appendicitis was positively made, and in that of rupture of the common duct it seemed probable that a perforated appendix would be found. The age of the patient and the history of previous attacks of indigestion and of severe colic made us think of the gall bladder as the source of the peritonitis, but concentration of the tenderness in the lower quadrant of the abdomen made it probable that an appendicitis was present. Both cases emphasize the fact that in the presence of peritonitis a doubt as to its source makes for, rather than against, the advisability of an operation.

I wish here to call attention to a sign which was referred to in the case of the ruptured duct before the incision was made, and one to which I believe attention has never before been directed. It is the localized jaundice of the umbilicus. Although a single case is not usually sufficient to warrant the assumption that something new has been observed, this feature was so marked that I can not refrain from believing that further observation will give to this localized jaundice some value as a sign of free bile in the peritoneal cavity. In the case presented, this feature gained in interest as the staining of the subperitoneal fat with bile was observed in the incision through the abdominal wall. The jaun-

dice is probably the result of inhibition. It makes itself manifest first in the integument of the navel, because this part is thinner than the rest of the abdominal wall.

It is possible, of course, that by reason of the anatomic relations of the round ligament of the liver to the transverse fissure there is a retrograde flow of bile through the lymphatics toward the navel, just as the *caput medusæ* is produced in cirrhosis.

Total gangrene of the gall bladder, to my knowledge, has not been observed, except in the case presented, as an affection independent of gallstones. Altogether, total gangrene of the gall bladder is a rare condition. Kehr and Korte⁶ do not mention it as an independent affection. Czerny¹⁰ describes two cases of gangrenous cholecystitis due to impaction of a stone in the cystic duct. Both patients were operated on, one successfully. Czerny¹⁰ ascribes the gangrene to pressure on the cystic artery, which, except for a very insignificant anastomosis along the attached surface of the gall bladder, is practically an end artery. In both of Czerny's cases the symptoms were those of intestinal obstruction. The gangrene was limited to the mucosa of the gall bladder. In 1894 Hotchkiss¹¹ found a gangrenous gall bladder by operation twenty-four hours after the onset of symptoms. A large stone was impacted in the cystic duct. No cultures were made. The patient died. Ferguson¹² reports a case of gangrene, in which operation was performed on the thirteenth day. Many stones were found. The contents of the gall bladder were sterile. Five weeks after the operation most of the gall bladder came away as a slough through the fistula.

In the case above reported, a most careful search failed to reveal the presence of a stone. Moynihan⁷ reports a case in which gangrene followed the involvement of the hepatic artery in carcinoma of the pancreas. The etiology of the case above reported is far from clear. There was no infection of the gall bladder at any time, at least not by aerobic bacteria. I believe that the gangrene resulted from occlusion of the cystic artery, although the manner of its obstruction must ever remain a matter of speculation. That it resulted from the excessive vomiting which marked the onset of the attack is more than probable. I am inclined to believe that by reason of this vomiting there was a twist in the neck of the gall bladder which involved the patulousness of both the cystic duct and artery. Theorizing may be in vain and even unprofitable, but it rarely lacks interest.

THE REGULATION OF PROSTITUTION.

* HOWARD A. KELLY, M.D.
BALTIMORE.

Every American traveling in the United States and everyone who goes abroad has often cause to blush when he finds useless and long worn out methods of various kinds introduced and seriously tested, to the great inconvenience of the body politic.

One of these systems, whose ominous mutterings I hear first in one part of the country and then in another, as it threatens to saddle its incubus on our long suffering people, is the regulation of prostitution by some sort of governmental sanction and control. Now, "*réglementation*" or regulation has been so thoroughly tested in

Europe, and with such conspicuous failure, that the Society of Sanitary and Moral Prophylaxis, of which the noted syphilographer, Dr. Prince A. Morrow, is now president, in taking up the question of dealing with the social evil and its attendant diseases, does not even propose to discuss at its meetings any papers advocating regulation. Surely our legislators, as well as those of our physicians who have but a limited knowledge and experience in such matters, can well afford to be guided in regard to them by the eminent experts who constitute the active members of the society and who hold this positive conviction without any bias whatever.¹

Given an evil, a sore on the body politic, the first impulse of the inexperienced enthusiast is to rush to the legislature to have a law enacted to the effect that the sore must not be there, or else that so long as the sore persists in remaining there, a committee of the legislature to have an emissary in the shape of a political doctor, shall pay the locality regular visits and spend valuable time in contemplating the sore, in order to see that it does not grow worse, with the idea, apparently, that a salutary restraining influence is thus exercised over it, through the high moral influence (*sic*) of his presence. In all this the twentieth century legislator recognizes unlimited graft, and he becomes an eager abettor of the callow philanthropist. This farce has gone so far, indeed, in the matter of the regulation of vice, that, had it not been for the women of our land, we should long since have been laboring in the slough of this most pernicious of all forms of legislation in every city in the land.

The only system as yet tried in this country is, as I have elsewhere said, that of utter indifference. As might have been anticipated, this has proved a disastrous failure, and we are in consequence called on to face the renewed efforts now being made to introduce another and even worse system, namely, that of regulation, which has so conspicuously failed elsewhere. It is saddening and disheartening to reflect that it is almost 2,000 years since we heard the fundamental declaration that "by the law is the knowledge of sin," while we stand here, in the midst of our boasted civilization, actually proposing that by the law sin shall be made safe and easy, corrupting the very standards of righteousness and justice at their fountain heads and placing the burden of proof that immorality is sin on him who would uphold right and purity.

If then experience at home has shown that indifference is a failure, and experience abroad has proved that regulation is no more successful, is there any remedy for this evil in our midst, and if so, what is it? A remedy there is, but it is not an easy remedy. It is of a drastic nature and acts on the whole system in order to purge this sore, cleansing the body of many noxious humors and sending good sound blood to the spot. This remedy is a sense of personal responsibility, which manifests itself under the form of an active, aggressive interest in this as well as in all other forms of right doing, by carrying on an unrelenting personal campaign against them, wherever and under whatever guise they may be found. A high standard of morals must be maintained in every avenue of life, for nothing is more certain than that this impurity cannot be removed, or even lessened, while the business and social life of the community remain corrupt in a thousand different ways.

Now simply to state that we need a higher standard of morals is but expressing the fact of the disease in different terms, and conveys no power of reform. We do not need knowledge, as some of us imagine; we need some transforming, regenerating power from without to enable us to accomplish that which our corrupt tendencies continually hinder. For this reason my own hope lies solely in God and in prevailing on men to look to Him for grace and strength to do that which they can not of themselves accomplish. Such a definite, real, personal approach to God is offered to us by our Christian faith, and where the faith is real it confers this power. "Sin shall not have dominion over you." But while it is eminently proper to point to this, in my belief, the one true remedy, the present is not the place for a full discussion of this subject.

If you tell me that the course I suggest is an impossibility I answer, neither is there any balm in Gilead for this wound. But if it can not be remedied, at least do not let us debauch public morals by making the very laws of the land panderers to vice; because our feet are in the mire is no reason why we should wade in waist deep.

Before leaving this subject of regulation I wish to present the translation of an important article which details the experience of an enthusiast for regulation, who carefully observed and studied the methods in vogue in Brussels and in Paris, and then had an opportunity of testing them while in an official position of his own at The Hague—I refer to Professor J. L. Chanfleury van Ijsselstein. I consider his testimony the more valuable because he was at the outset, as I have said, an ardent advocate of regulation and entered on his career with enthusiasm, yet he speaks here, after some years' experience, as a converted skeptic.

If regulation, tested under such favorable circumstances, has failed in a country where law is, in some degree at least, respected, how can a like plan succeed in a country like ours, where the very term legislator has become a byword for corruption; where laws are made to be evaded and set aside by expensive processes, quibbling, and disheartening delays, and where every man does that which is right in his own eyes.

I quote Professor van Ijsselstein, therefore, hoping that his experience may prove "a word to the wise."

THE REGULATION OF PROSTITUTION FROM THE POINT OF VIEW OF PUBLIC HYGIENE.

BY PROF. J. L. CHANFLEURY VAN IJSSELSTEIN, GENEVA, 1889.

Regulation of prostitution was first established in the hope of restricting the extension of venereal disease. By such means it was hoped that infections would be traced to their origin, and the public thus protected against diseases which incontestable experience shows are productive of the most formidable consequences. This is done by isolating the infected women and thus making it impossible for them to injure others. As it is, even persons whose habits of life forbid us to imagine that they have acquired an infection through their own fault, are not insured against it, but must often suffer for the sins of others.

Such an object is surely a praiseworthy one, and there is no reason why we should, as we are too easily tempted to do, assume a less honorable motive in the establishment of regulation. If our food and drink are subjected to a minute analysis in order to detect adulteration and prevent disease, it might be thought that in the very name of justice, women, considered as necessary to the satisfaction of the sexual instinct, might be regarded as equally adapted to protective measures. From this point of view the authorities might well wish to manifest their foresight by placing the means of healthy coitus, as well as of healthy nourishment, at the disposal of the public.

In any discussion as to the efficacy of regulation, such motives should be regarded as beneath the dignity of those in authority, as well as of the physicians in charge of this service.

1. "What is the Right Attitude of the Medical Profession Toward the Social Evil?" THE JOURNAL A. M. A., March 4, 1905. "The Best Way to Treat the Social Evil," Med. News, June 23, 1905.

The purpose of our undertaking is to inquire, as far as possible, into the results of the regulation of prostitution from a medical point of view. To accomplish this end we must determine the conditions under which examinations should be made, and ascertain what infections should be considered as dangerous or suspicious. We must also, of course, inquire whether the medical officials in charge of the examinations are really of the highest standing in their profession. The following question has for a long time awaited an answer: Does or does not the periodical examination of prostitutes afford sufficient guarantee against contagion? The gist of the whole matter is, indeed, contained in it, for a medical examination which gives no security against contamination is probably productive of more harm than good.

In order that examinations shall afford a sufficient guarantee against possible contagion, it must be possible to isolate, not only the women affected with contagious venereal disease, but also those under suspicion of it. Therefore, not only all prostitutes who present unmistakable evidence of infection, but also all those who require to be kept under observation because their true condition can only be determined by subsequent examination, must be restrained from the exercise of their profession. All cases of primary syphilis must be isolated, and also all cases of secondary syphilis in the condylomatous stage. In other words, every woman who has a primary lesion, or in whom it is suspected, must be restrained from spreading infection, and also every woman who presents condylomatous symptoms, or who is passing through the condylomatous stage of the disease, even without the external manifestations of it.

Every erosion, vesicular or pustular, and also every congestion or turgescence which resembles the first stage of an initial sclerosis, on whatever part of the body it may occur, must be suspected of being a primary lesion. It is impossible to designate any characteristic sign by which these manifestations can be distinguished from those which are not contagious; even their situation is only a relative indication of their nature. Isolation of the affected person is essential, because it is only by further observation that the real specific character of the disease can be determined.

In constitutional syphilis, mucous patches and everything resembling them must be considered as potentially contagious. Thus an eczema interigo, situated not only on the genital organs, but between the fingers or toes, may conceal a mucous patch. In the same way a trivial redness at the corner of the mouth, on the tongue, or, above all, in the region of the tonsils, which is, at first, indistinguishable from a catarrhal affection, may be the earliest appearance of a mucous patch and fully as contagious. This is why it is hard to distinguish mucous patches from the lesions characterized under the name *leucoplakia*. This latter affection, which is of long duration, should always be regarded as suspicious. Indeed, women passing through the condylomatous stage are dangerous, even without external evidence of it, for they can contaminate through both the blood and the secretions.

From the point of view of risk of contagion, it is important to note that it is exactly the more obvious manifestations, such as syphilitic lupus and other later ulcerative indications which are least contagious or not contagious at all. The majority of syphilitic manifestations are barely perceptible or extremely mild in appearance. There is, of course, an exception in the fact that latent syphilis can be communicated during the condylomatous period, for incontestable cases of it have been established. And in the presence of so dangerous a disease all exceptions must receive careful attention, above all if in so doing we secure ourselves more surely against infection. Blenorrhagic affections are of no less importance. It is claimed that they do not, like syphilis, induce blood poisoning. This is incontestable, but they are none the less capable of sometimes poisoning the lives of persons afflicted with them. Moreover, the numerous sequelae, whether mild or severe, which may result from blenorrhagia, are well known. The most frequent of these is stricture of the urethra. I have known persons whose whole existence was made miserable by reason of this infirmity, in spite of the most skillful treatment. They failed to achieve the social position to which they might have aspired and fell victims to premature death. It is unnecessary to enumerate the serious inconveniences and organic troubles which result from stricture, for every practitioner has had opportunities to observe them.

Blenorrhagia in women is extremely difficult to establish. It is very hard to discover the existence of a chronic urethritis in a prostitute, if she has taken care to remove the secretions immediately before examination, yet such an urethritis retains its capacity to infect for a long time. It should be sus-

pected whenever continuous pressure on the female urethra occasions the escape of even a small amount of mucus, for it has often seemed to me that even this slight degree of the affection was sufficient to communicate blenorrhagia to men. Moreover, it must be noted that whenever a woman has once been affected with contagious blenorrhagia she can communicate the infection by means of coitus for a very long time, a much longer period, indeed, than is the case with men.

The same thing occurs in affections of the neck of the uterus. When the secretions from the cervical canal are not clear, or when they do not remain clear in spite of excitation, the physician must be on his guard. Every expert recognizes that in this respect very few prostitutes are in favorable condition.

All these considerations show that a well-conducted medical examination is a most onerous undertaking, which demands practical knowledge, and which depends for its success on the discovery of the slightest trace of infection. It is hardly necessary to add that much time must not be permitted to elapse between the examinations. An examination every day would not be excessive.

I am well aware that these matters are not usually considered in this light, but when I relate the observations which I myself have been able to make, the reader must certainly acknowledge that the subject is commonly treated much too lightly.

Some years ago I went to Paris and to Brussels for the special purpose of studying this question as thoroughly as possible. These two cities had, at that time, the reputation of carrying out the method of official control and treatment of prostitutes in the best possible manner. I had opportunities to observe the examination of prostitutes at the *bureau des mœurs* in Paris and of following attentively the methods employed by the medical men. I was also present during the examinations at the public brothels, and I feel it right to say that a large number of women were examined in a manner so superficial that I was astonished. The inspection was limited, in general, to the genitalia, and consisted principally in a rapid use of the speculum. The examination of each woman did not occupy, altogether, more than two minutes. In Brussels the methods were somewhat more careful, but there also they were very far from irreproachable on the score of exactitude. I was also struck with the absence of the serious attention which should always accompany so grave an occasion. At the examination of the brothels, in particular, I noted that the demeanor of the physicians left much to be desired from the point of view of dignity. These observations, it is true, were made more than forty years ago, and matters may now be improved.

On returning from my tour of inspection, I made no delay in seeking an opportunity of applying the knowledge I had just acquired, and I was placed in charge of the examinations at The Hague.

I applied myself courageously to my task, with all the ardor of a young practitioner who sees a new career opening before him, and whose zeal is stimulated by the feeling that an important branch of public hygiene is committed to his care. There was, at that time, no opposition to the application of energetic measures. The authorities had but one object in view, and they had not yet perceived that regulation of prostitution might contain anything contrary to individual liberty. Even minors were subjected to examination. Prostitutes who presented themselves at the place appointed for the purpose were examined under my own eye by an attendant physician. I myself made examinations in the public houses at hours not made known beforehand. The entire person was inspected with the utmost care, and the slightest appearance suggestive of infection was made the subject of investigation.

And what were the results of these examinations, conducted, as they were, with the utmost severity? They were so far from satisfactory that at the end of several years I became convinced that I ought to ask to be relieved from an undertaking which was apparently entirely wanting in the usefulness to the public health expected from it in the beginning. How were these negative results to be explained? By the fact that a medical examination, no matter how carefully conducted, affords no guarantee whatever against contagion. In the course of my unexpected visits to brothels I was obliged to send some two-thirds of the women examined to hospitals, either because they were infected or because they were suspected of being so. And even then I was not secure of the remaining third, although they could not be retired, because it would have been dangerous to empty the public houses of debauch. Moreover, the severe measures which had been taken aroused the whole body of prostitutes to resistance, and I could not make my evening visit to the hospital without a po-

lice escort, so much reason was there to fear that the numerous anonymous threats addressed to me would be put into execution.

It should once more be noted that at this period the contagiousness of syphilis through the blood and secretions of a patient in the condylomatous stage was not yet demonstrated. A knowledge of this fact would have led me to withdraw a much larger number of suspected persons. It is now so well established that I would not be willing to accept the responsibility of giving a clean bill of health to anyone whom I had examined, in ignorance of her previous history. Security can be attained only by isolating the patient and keeping her under observation during a given time.

From all that has been said I feel myself justified in drawing the conclusion that such a thing as a safe public prostitute does not exist.

It may perhaps be urged that although compulsory examination does not withdraw all infected women, it is nevertheless a step in the right direction, for by isolating the more dangerous cases protection is afforded to many who would otherwise be infected. And it is claimed that, although regulation may not succeed in exterminating the evil growth, it at least prevents its multiplication to such an extent as to stifle useful plants. This reasoning has, perhaps, a certain plausibility, but it is of no value here. It is, of course, a fact that the number of men who avail themselves of prostitution increases considerably as soon as the public knows that it is under control. A great many men, who are kept away from brothels by fear of contagion, resort freely to them if this dread is removed, believing that they can profit by such a favorable opportunity with security. I saw clearly, when at the *Flague*, that the attendance at the public houses increased as soon as the report spread that I was in charge of the examinations. Therefore, the numbers only increased instead of diminishing, in consequence of the elimination of so many unsafe subjects. And yet, in spite of the minuteness with which the examinations were made, a certain number of persons who had remained abstinent up to that time contracted venereal disease.

All contagion which occurs in houses under the control of the authorities is a proof of the inadequacy of the system of sanitary examination; this places the gravest responsibility on those who institute compulsory examinations and those who conduct them.

Statistics have been called in to assist in showing that regulation has reduced the total number of sufferers from venereal disease. This point calls for some comment founded on facts. Speaking generally, statistics are a source of information as to the quantity of disease rather than its quality, and in this particular case the fact is especially true, for the two following reasons:

In the first place, statistics are not without reproach in the matter of nomenclature. The terms under which diseases are classified in statistical statements have no solid basis. A common tumor or a simple herpes which has undergone ulceration may very easily be diagnosed as a soft chancre, if it occurs on a suspicious part of the person. The same thing occurs with neglected erosions or ulcerated lupus. In how many cases of autoinoculation does it not happen that a recent diagnosis is demonstrated as false, although it has appeared in the statistics? How many times has the diagnosis of so-called specific induration characterizing an initial sclerosis been falsified, because the symptoms of constitutional syphilis did not appear within the usual limits? In regard to blennorrhagia also, the statistics are very uncertain. All persons affected with stricture of the urethra preserve during the remainder of life, in differing degrees, an irritability of the part of the canal just behind the stricture. With such patients a little investigation is sufficient to demonstrate a mucopurulent secretion, most frequently slight in amount. Such patients frequently experience a more abundant discharge in consequence of the superexcitation occasioned by coitus, and this is carefully noted as a fresh attack of blennorrhagia. Such blennorrhagias furnish a rich harvest to the compilers of statistics. They are noted under the head of venereal disease, where they produce a vivid impression and exaggerate the importance of the real centers of infection.

It may then be asked: Who are the patients who figure in statistical statements? Only those treated in public establishments and hospitals. The majority, who conceal their ailments, do not enter into statistical reports at all. This disinclination of disease, which constitutes the principal obstacle to effective treatment, is the reason why no confidence can be placed in figures representing an increase or decrease of contagion.

There is no doubt, however, that medical examinations, even when conducted in a superficial manner, ought always to suppress some centers of infection. When public houses of debauchery are not under control, there will, very likely, be a greater number of infections among their habitués, and it is not impossible that statistics may represent these correctly. But what statistics do not represent is the number of unfortunate who contract disease in places which they are induced to visit through a misplaced confidence inspired by regulation. Statistics are also silent as to the number of persons who do not seek relief at public institutions.

It is, then, an unsettled question whether the victims of insufficient examinations do not rather incline the balance to the other side and really establish that regulation which increases the total number of cases of disease.

Beside the intrinsic difficulties of regulation which I have just enumerated, some attention must be given to the personal qualifications of the men in charge of this department of public hygiene. There is no doubt that they ought to occupy a high position, both morally and intellectually, yet it is only too certain that their social status is not an enviable one. The public in general forgets that they assume the responsibility of a most important service to the public health, and that they are entitled to universal esteem if they acquit themselves creditably of their duties. All these considerations occasion a legitimate doubt whether it is possible to find officials capable of conducting examinations in a conscientious manner; and we may also inquire whether municipalities are accustomed to offer medical men an honorarium sufficiently large to compensate them for the professional loss occasioned by the exercise of their office.

If all these points are taken into consideration, namely, the unavoidable inadequacy of examinations, even if repeated every day, the difficulty of procuring officials competent to conduct them, and the great expense involved in doing so, we are justified in condemning a system which presents so many objections against such extremely problematical advantages.

If it is conceded that the method at present in use is of no value, we must inquire whether there is any other way of preventing the evil done by prostitution to the public health. Assuredly, the abolition of compulsory examination will not in itself attain this end, especially if things are allowed to take their course in other respects. There will always remain a risk of contagion, not only for persons who allow themselves to be seduced by the opportunities afforded in public prostitution, but also for those victims who create such occasions indirectly through their own misconduct. It is necessary to go further and abolish completely the establishment of public resorts for debauchery, as well as all public prostitution. This is the surest means of destroying infectious centers. I am aware that such a proposition is likely to be greeted by loud outcries, so great is the dread of clandestine prostitution, and of the disastrous effects attributed to it on the public health. Clandestine prostitution has always been the great obstacle to the adjustment of this question of regulation. But have the facts been sufficiently examined? Is it really established that clandestine prostitution is as dangerous as it is supposed to be? For my own part I think we are at liberty to doubt. In order to answer the question it is essential to understand exactly what constitutes clandestine prostitution and what objections it presents in comparison with public prostitution.

Clandestine prostitution includes all women who sell themselves for purposes of debauchery, without, however, being at the service of all comers and at all times. For this very reason such a class of persons presents less danger to the public health. The clients, who are known to the prostitutes personally, prefer, for one reason or another, to have intercourse with a single woman, to whom they are often attached. If such a woman contracts disease, the client soon becomes aware of it, and he can protect himself against its extension.

With public prostitution, on the contrary, things are quite different. Women who practice it are at the disposition of every comer at any time; their houses are veritable dens of debauchery, where liquor is employed, as a matter of course, to destroy men's will power and drive them to commit irreparable sins. Lastly, does not observation teach us that venereal patients who present themselves at clinics or at public hospitals have most frequently contracted disease through frequenting public houses of prostitution? It is when they are overcome with liquor that these unfortunate lose all distrust, and do what they bitterly regret when they come to themselves. If there were not so many public temptations many of these men would escape such a fate. I could cite many more facts, taken from my own experience, in support of what I urge, but what I have already said seems to me sufficient to prove

that the suppression of public prostitution would, on the whole, be a benefit to public health.

If we wish to contend with this terrible class of diseases, it is above all necessary that venereal patients should have medical attendance at their disposal. The system in action up to the present time alienates these patients through fear of reprobation or of punishment, while it should, on the contrary, take into consideration only their sufferings and hold itself aloof from the misconduct which has occasioned them. The patient should no longer be withheld from seeking the necessary assistance by unwarrantable restrictions. Measures of relief should be distributed with a liberal hand. By these means positive results will be obtained of infinitely more service than the total uncertainty attending the system now in action, which I do not hesitate to oppose.

AMPUTATIONS BELOW THE KNEE.

C. B. CLAPP, M.D.

Surgeon in Charge, Wabash Employes' Hospital.

MOORELY, MO.

There is little in this subject of technical interest to the surgeon of to-day; it is such an old subject, its technic is so familiar and its performance so simple. Surgeons are looking for greater things, therefore the immediate result is about all they observe and but seldom stop to consider carefully the most important question relative to these amputations, the ultimate usefulness of the stump.

Having been called on three times during the past year to make leg amputations where the Chopart stump was so painful that use was impossible, having also noted the wide differences of opinion among surgeons and also among artificial limb makers, as to the value of these various amputations, I resolved to secure the opinion of the most practical and to compare notes.

I addressed circular letters to 100 surgeons and 35 limb makers, receiving reply from 96 surgeons and all of the latter. The following is a brief summary of these replies:

QUESTIONS ADDRESSED TO ONE HUNDRED SURGEONS.

1. "Where it is possible, would you advise the *Lisfranc* amputation or any of its modifications?"

Twenty-four answered "No," 4 answered "Yes" conditionally, and 63 "Yes," many of the latter indicating a preference for the Hey modification.

Of these amputations 364 were reported to me with slightly over 20 per cent. reported as "unsatisfactory" and 7 had sought amputation of the leg.

2. "Where it is possible, would you advise the *Chopart*, *Pirogoff*, *Symes* or any other amputation through the foot?"

(A) CHOPART: Fifty-seven answered "No," and 34 answered "Providing there is plenty of plantar tissue accessible, Yes."

Of 241 cases reported, over 73 per cent. were reported as "unsatisfactory," and 47 had sought amputations higher up.

(B) PIROGOFF: Sixty-six answered "No," and 22 answered "Yes."

Of 152 cases reported, nearly 61 per cent. were reported "unsatisfactory," and 18 had sought amputation of the leg.

(C) SYMES: Seventy-six answered "No," and only 9 answered "Yes."

Forty-three cases were reported with 9 "unsatisfactory," and 2 of these had sought amputation of the leg.

3. "Where the foot must come off, where would you elect to amputate?"

Seven answered "at ankle joint"; 14 "as low as possible"; 9 "three inches above ankle joint"; 16 "just above middle lower third"; 12 "junction of upper with middle third"; and 46 "junction of lower with middle third."

Fifty-eight of these surgeons reported having made over 1,200 amputations, the remainder had no available records.

QUESTIONS ADDRESSED TO THIRTY-FIVE LIMB MAKERS.

1. "Can artificial appliances be made useful in the *Lisfranc* amputation of the foot or its modifications?"

Twenty-six answered "Yes"; 4 answered "They can, but they are not always satisfactory, as patients frequently return complaining of pain and are unable to walk"; while 5 answered positively "No."

2. "Can artificial appliances be made useful, as to restoration of gait and usefulness of foot in amputations through the foot as in *Chopart*, *Pirogoff*, *Symes* and other methods?"

(A) CHOPART: Twenty-four answered "No," and 9 answered "Yes."

Many of those answering in the negative gave as their reasons that "Surgeons are not careful enough in making such amputations," and that "the scar is often adherent, not far enough back, and the stump is extended."

(B) PIROGOFF: Five answered "Yes, in selected cases," while 26 answered "No."

(C) SYMES: Twenty-two answered "Yes," and 9 answered "No, except in selected cases."

3. "If the foot must come off, where should the amputation be made?"

The universal answer was "from six to nine inches below knee, measuring from lower border of patella."

4. "What kind of flap makes the best stump for fitting an artificial limb?"

Nearly all of them answered "Long anterior with short posterior, bringing the scar well back with loose normal skin covering end of bone."

Sad differences of opinion are at once seen. Surgeons differing with each other and limb makers with each other, and the one class differing with the other on many vital points. This is especially noticeable concerning the *Symes* amputation, where 76 surgeons advise against the operation, with 9 in favor of it, while 21 limb makers favor the resulting stump, to 9 who do not, except in selected cases.

As surgeons, we must recognize the wide experience and ability of our best artificial limb manufacturers. They see the patient many times after we have lost sight of him; in fact, he is forever haunting them with all his misfortune. The question that should engage our serious consideration is: Where and how shall we amputate? considering carefully the future comfort, physical requirements and the possibilities of our patient.

Dr. Fred Murphy of Boston, after making his "Study of Amputations of the Lower Extremity," says: "In going over this subject exhaustively, I found that surgeons themselves had very little idea of the after results in these cases." He also says: "Before my investigation I was enthusiastic as to the value of partial amputations of the foot, but after seeing and talking with the patients I was forced to believe, that as a routine, there is nothing so satisfactory as a good tibial stump of medium length." Again he says: "The makers of artificial limbs tell fine stories about the apparatus that they can fit to these partial amputations, but with very few exceptions they have, in my experience, proved to be most unsatisfactory."

The prevailing complaints among the limb makers against the partial amputations of the foot are "weak supporting arch," "extension of stump," and "insufficient flap and faulty position of scar, which is often adherent and tender."

The old theory of saving all that you can, applied to amputations below the knee, is certainly very absurd, and no intelligent surgeon of to-day would give it even a passing thought.

I believe that no partial amputation of the foot should be made which does not afford sufficient plantar bearing surface to carry the entire weight of the body, with

ample flap to form loose covering over end stump and to bring scar well back out of line of pressure. I believe that an ideal leg amputation is superior to many Chopart or Symes and most Pirogoff amputations. The Lisfranc, especially the Hey modification, gives a very satisfactory stump. I wish to suggest, however, that in making this amputation, it is wise to preserve the attachment of the tibialis anticus, when possible, and if not, to attach its tendons to the plantar flap. This same rule applies also to the peroneus tertius.

In making amputations of the leg, there are a few important details which we should not lose sight of:

1. Be certain of sufficient flap to properly cover end of bone, regardless of how close this may come to the knee joint. Flap must be considered first, length of stump second.

2. The most uniform good results are obtained by making the long anterior with short posterior flap, bringing the scar well away from end of stump.

3. Redundancy is always undesirable.

4. When the length of stump is at the discretion of the operator, it should be from six to nine inches below border of patella.

5. Periosteal flap with coaptation of muscles over end of bone is always desirable.

6. Always cut the fibula one inch shorter than the tibia and when the amputation is near the knee joint, disarticulate and remove the fibula.

7. In all these amputations, nerves should be drawn out and cut as short as possible.

THE EVILS OF PROPRIETARY MEDICINES.*

JOSEPH A. PETTIT, M.D.
PORTLAND, ORE.

Many preparations are passed off on our profession by apparently reliable manufacturing houses as ethical proprietary preparations or as definite, synthetical compounds that are not only simple nostrums, but some may be classed as base deceptions. The unsuspicious physician is victimized by these deceptions, is misled by their advertising literature termed "modern therapeutics," and prescribes for his trusting patients these advertised remedies, which are high in price and of whose composition he is either partly or wholly ignorant.

The nostrum evil flourishes more in this country than in any other. To classify the many proprietary preparations, to sift the true from the false, the really ethical from the no-strum, is a difficult matter.

Some medicines are patented, which protects the patentee for seventeen years, but these are not secret, because from the patent office anyone can obtain the description, composition and the method of manufacture. The patent serves simply to increase the cost to the consumer by giving one manufacturer the exclusive right to manufacture the article.

According to the dictionary, a nostrum is "a medicine, the ingredients of which are kept secret for the purpose of restricting profits of sale to the inventor or proprietor; a quack medicine." In this pernicious class are those preparations that are protected by trademark or copyrighted name, and the composition of which is either kept absolutely secret, or there is a pretense of a formula. This secrecy or semi-secrecy is really considered of little moment by the manufacturer, who lays his main stress on expounding the indications

for the use of the remedy in a long list of symptoms and ailments which are equally legible to the uneducated and educated in medical matters.

There are two kinds of nostrums and there is no difference between them technically—the secret proprietary preparations manufactured for physicians and advertised lavishly in the medical press, and the common "patent medicines" advertised in the public press. On the one hand the indications for use are couched in medical language, as "Dioiburnia," or "Hayden's Viburnum Compound is the most beneficial remedy known to medical science for dysmenorrhea," etc.; and on the other hand, the wonderful usefulness of the recent marvelous discovery is explained in the language of the public as "Lydia E. Pinkham's Vegetable Compound absolutely cures painful monthly periods and elevates a fallen womb."

The physician abhors the patent medicine evil; yet he reads the literature of the proprietary manufacturers, exploiting their wares, and follows their directions in prescribing to his trusting patients. He is simply being used as a middle-man to distribute these "cure-alls" to the public in general. He is paving the way for ultimate counter-prescribing and ultimate self-medication.

It is difficult to understand why we call medicines and preparations that are advertised in newspapers "patent medicines," and those that are advertised in medical journals "proprietary" or "ethical," when the claims of the two are so much alike and the degree of secrecy equal. The layman can naturally accuse the physician of making a distinction without a difference. Some are so bold and brazen as to make no attempt to tell what the nostrum is, whether it is some real drug or nothing but dirt and syrup. Others make a pretense of giving a formula, with or without amounts. They may give the true formula or simply "a formula" or no formula whatever—not for the benefit of the prescribing physician, but to make the article more easily salable through the medical profession and more profitable to themselves. A favorite and successful method is to give a list of ten or twelve drugs, about two of which are common ones of definite known value that we all use, and the others inert, useless ones with high-sounding and unfamiliar names—the latter serving as a cloak for the formula and giving the impression of some great and potent mixture, "the result of years of medical research." The most dangerous of evils lurk in such deceptions.

A manufacturer of drugs in general and nostrums on the side, as so-called specialties, who uses such methods may justly be the subject of suspicion in all his products. Matters of truth, veracity, honesty and efficiency are of little importance. The sole aim of such manufacturers is to make a product salable and as profitable to themselves as possible. An illustration of their veracity and reliability can be gained by a quotation from THE JOURNAL of the American Medical Association of a recent incident:

A firm which had been making a proprietary tablet for years had published a certain formula; recently they changed this by adding eight grains of another drug. The pharmacist in question made inquiries of several chemists about this drug and they all assured him that they had never heard of it. He then wrote to the manufacturers of the tablet, asking them if they had changed the ingredients of their preparation, and they made the following reply: "We have not changed the tablet, we only changed the published formula." We wonder how often the opposite is true, that the published formula remains as it was while the ingredients are changed.

* Read before the Eastern Hospital Graduates Club and the Lane County Medical Society.

Most nostrums of any value depend on some common drug familiar to us all and which we could use readily ourselves in prescription compounding, and the unwary physician is captured by the long named extra drugs added, for which wonderful powers are claimed, but which really are inert, or at most, unimportant in their actions.

Let me quote an illustration given by H. C. Wood, Jr.:

Let me call attention to one other example of this effort to confuse the unwary, the simplicity of which is really laughable. A very extensively advertised drug, hailing like other orthodox fakes from St. Louis, is said to be "a palatable preparation of *Panax schinseng*." *Panax* is the botanical name for the popular Chinese remedy ginseng, whose therapeutic value is about equivalent to that of licorice root. If you want licorice, order extractum glycyrrhizæ.

The bombastic descriptions which the vendors furnish of their strictly original methods of manufacture, dwelling in flights of ambiguous verbosity regarding the special action of enzymes and the special processes of metabolism, etc., of their remarkable products is at once unintelligible and misleading to the general practitioner. Only an expert, conversant in the recent vocabulary of the theories of immunity, etc., can discern the little truth in some of the descriptions and the deceptions of most of them. Meanwhile the vendor revels in the profits of the sale of his wares and laughs in secret—and sometimes openly—at the simple credulity of educated men whom he can so easily dupe.

A Scotchman once said that he had been taught that there were five senses—seeing, smelling, etc., but he knew that there was a "sixth sense," called common sense, and many people, both educated and uneducated, do not have it.

In extolling the high characters of their products the manufacturers frequently speak of the thousands of dollars spent in perfecting this or that remarkable remedy. But, we may ask, did they have an opportunity of trying it on patients? The money may have been spent, but the "perfecting" has been the "perfecting" of the business side by the suborning of journals, by printing attractive literature, and by hiring detail men to go around and leave samples and make long "spiels" like a vendor on the Portland Trail or the St. Louis Pike.

The manufacturers of proprietary preparations are banded together in the Proprietary Association of America and have appointed a very active press committee. They realize that it will mean to them the loss of millions if the medical profession and the laity are given the light of publicity on their work and their methods, and, in the case of the former, if each doctor is educated to write his own prescriptions. They have exerted every method of vigilance possible and have endeavored to flank every move that has been made toward publicity. Their subsidized medical journals (and this includes about half the medical journals in this country) have suppressed the exposures of the coal-tar products, as made in the report of the Council on Pharmacy and Chemistry of the American Medical Association, and have been able to bring to bear sufficient influence to induce some of these journals to take their side editorially.

Early last winter an editorial appeared in the *Vermont Monthly Magazine* advocating the use of secret remedies, and this article was widely distributed throughout the country by the nostrum proprietors. And this magazine is the official organ of the Vermont State Medical Society.¹

After the exposures of the composition of phenalgin by the council of the American Medical Association the company manufacturing this article had a two-page advertisement for two issues in the *New York Medical Record* denying the fact that their product was a simple mixture of acetanilid, sodium bicarbonate and ammonium carbonate, as shown by the Council on Pharmacy, and indirectly still claimed it to be a definite synthetic chemical substance, and, furthermore, went on to slur the said council and its work and the American Medical Association in general. The *JOURNAL* of the American Medical Association wrote to the editor of the *Medical Record*, calling his attention to these insults in its advertising pages, to which Dr. Thomas L. Stedman, the editor, replied that the editorial pages of his journal and the advertising pages are "separate and distinct."

Through the above report the profession was long ago informed of the composition of ammonol. Yet a few days ago I received samples and the usual literature (which allowance was doubtless sent at the same time to every physician in the country) of ammonol—"stimulant"—"ethical"; "the only antipyretic and analgesic that not only does not depress, but actually sustains the patient." "The administration of ammonol in typhoid is imperative, not merely because it is invaluable to reduce the temperature, but because it is antiseptic and has a decided action on the digestive tract."

Not many physicians would prescribe acetanilid in typhoid, and yet, beguiled by the deceptive description of a nostrum, will prescribe contrary to their own judgment.

According to the advertisement, "salacatin is a combination with heat of salicylic and glacial acetic acids with phenylamine, the irritating, depressing and blood corpuscle destroying elements removed."

According to the committee of the American Medical Association, "Salacatin" is a mixture of acetanilid, salicylate of sodium and bicarbonate of sodium. Sal-co-deia-Bell (Salacatin-codin), therefore, would be the same as the above with codin added.

This shows that their claims, to the effect that salacatin is a definite compound, are false, and that it is a simple, common, ordinary mixture.

A sample of the similarity between "patent" and "proprietary" medicines may be gleaned from the policy of the company which exploits "Kutnow's Powder." In England it appears to be advertised in the daily papers as peruna is in America, with recommendations of various celebrities, even to physicians. In the United States it is advanced as a "proprietary" medicine and is handed out to the public through the agency of the medical profession. In the English dailies numerous testimonials appear from American doctors, and its claims are just as extravagant as are those of any other extensively advertised "patent medicine." The analysis of it shows it is simply an artificial Carlsbad salts.

Recently an analysis of a cod-liver oil preparation was made by some chemists, who reported on it as follows:

We recently had occasion to open a package of a well known preparation of "Tasteless Cod Liver Oil." The circular which was wrapped around the bottle was replete with interesting information, especially for the patient, who obtains the preparation in the original package as prescribed by the physician. He finds in it a list of the diseases in which the preparation does wonders; they range from dread consumption to cystitis and hemorrhage of the kidney. Most interesting to us, however, is the statement that the compound "contains all the necessary elements of nutrition." It is too bad to disturb this beautiful vision by a report of the chemist. This shows that the product is quite free from oil or proteids; the only nutri-

1. Since the above was written, the *Vermont Medical Journal* has evidently gotten into new hands, and is now standing for better things.

tive ingredients are perhaps alcohol, sugar and glycerin. But the claims of the manufacturer are probably correct, because it contains carbon, hydrogen, oxygen and probably a trace of nitrogen—so does gunpowder. Perhaps it will now be the turn of strychnin to be advertised as the ideal food. It seems superfluous to point out the moral of this tale.

The most extravagant claims are made regarding the clay mixtures. The circulars pronounce them practically cure-alls for all ailments from inflammation of the pelvic organs to tuberculosis. Their claims are largely without foundation, and as a poultice they do not come up in efficiency to the common flaxseed meal. The clay is absolutely inert from a therapeutic standpoint. The essential oils and antiseptics are combined in such infinitesimally small proportions as to be of no value. The anhydrous glycerin, as we all know, has a hygroscopic action, and herein lies the small and only virtue of these clay poultices.

Dr. Roth of Ann Arbor has conducted experiments with the clay mixtures in regard to their heat-retaining powers, one of which I will quote herein in detail:

Two one-pound cans were taken, one filled with the clay mixture and the other with flaxseed poultice. Both were heated to 80 degrees C. They were now placed side by side so that all conditions were equal and the temperature taken every hour to determine which gave up its heat the sooner.

	Clay mixture.	Flaxseed poultice.
	80 C.	80 C.
After 1 hour.....	40	40
After 3 hours.....	21	27.5

The clay mixture gave up its heat in three hours, at the end of that time being at the room temperature of 21 degrees C., while the flaxseed mixture at this time still had a temperature of 27.5 degrees C. It is evident, then, that by means of a flaxseed poultice heat and moisture can be applied for a longer period than by means of the clay mixture, and this fact stamps the flaxseed poultice as more efficient than the clay mixture.

One of the most smooth nostrums and one which on the surface is apparently ethical, but yet which is revealed by analysis to be one of the most rank, advocates (as does peruna) a cure for catarrah (that great catch word) of any part of the body.

There is no pretense of any frankness whatsoever as to its composition. Its price rivals that of holy water, yet the water in it (of which it is composed with a very little glycerin and coloring matter and some of the common, well-known alkaline salts) is only common well or river water, whose only magic is that it comes from New York. Why should we pay a dollar a pound for a nostrum about which we know nothing and prescribe it under a trade name that will soon become common property and indefinitely add riches to the coffers of a shrewd manufacturing company, when we can really compound a superior mixture for the large sum of one and one-half cents? We should not debase our own intelligent prescribing by acting as a middle-man for the sale of some peddler's wares, inferior in quality and exorbitant in price.

By taking nine of those tablets called the "alkaline and antiseptic nasal tablets," made according to the formula of Seiler, and nine drams of glycerin and sixteen ounces of ordinary good water practically the same thing is secured, minus a little coloring matter, which it is really well to omit. The strength of this can be readily and easily increased or decreased by adding or lessening the number of tablets. To make it look sensational one may add some coloring and then cut out a well-known picture and paste it on the bottle; the picture of a lovely lady pouring some of this delightful potion from a gracefully-shaped glass container into the cavity of her aquiline nose.

Another prescription, efficacious, handy and useful, might be written thus (and it can be changed at will to suit the individual requirements of each particular case):

R. Thymol gr. i-ii	107-13
Sodii bicarb..... 5ss	15
Sodii salicylat..... 5iii	8
Sod. biborat, (borat)..... 5iiss	45

Sig.: Teaspoonful (more or less as sensitiveness of mucous membrane indicates), dissolve in one-half cup warm water, and use as a nasal douche or throat gargle.

In regard to this "great discovery," physicians will after a time awaken to its nostrum deception and cast it off along the lines I have suggested. But meanwhile the company will have become enriched financially and will have gathered in thousands of testimonials of unwary physicians, and then will begin an ordinary peruna public record with the laity.

In Porto Rico a commission was appointed to investigate the disease known as uncinaria and to report the results of treatment of same. They reported a long series of cases of anemia from uncinariasis and the results of their treatment with three different iron preparations, Bland's pills, Vallet's mass and Gude's pepto-mangan, the latter being furnished them by the exploiters, M. J. Breitenbach Co. The commission reported that the patients improved the fastest on the Bland's pills, the next on Vallet's mass, and the slowest improvement was those on whom pepto-mangan was used. In fact, four of the eighteen cases which were treated with pepto-mangan had improved so slowly that they were finally put on Bland's pills.

The commission informed the pepto-mangan people of the result of their investigations, and yet, in the face of this report, the company published a long article and circulated it among the profession of the country, stating the work of the commission, that they had found pepto-mangan superior to all iron preparations tried, and that this convincing proof should influence all medical men to use this valuable remedy in all of their cases of anemia.

In conclusion, let us consider first the causes of this deplorable condition to which the therapeutic standard of our profession has been lowered by the commercialism and vandalism of selfish "shell game" proprietary manufacturers.

Doctors are only American people, and a scanty, hastily acquired medical education still leaves them Americans, of whom a good judge of human nature once said, "they love to be duped." Their thoughtlessness and lack of therapeutic knowledge make them ready victims for the shrewd and persistent advertising of the master of that wily art, the nostrum man. The deplorable condition referred to is brought about in the first place through the agency of the subsidized medical press, which gives up not only its advertising pages, but half its reading matter for the love of gold, and publishes what the editors must know is false and fakish; by means of attractive literature and alluring testimonials; through the agency of suave detail men with samples and urgent requests to "try our products"—each bunch of samples covering the necessities of most all diseases.

The doctors, too, are at fault; their ignorance of pharmacy and prescription writing is the crux of the matter—we might say their judgment and discernment are deficient. The blame for this may be laid to deficient teaching of therapeutics in the medical college. The mental apathy of the average physician along therapeutic lines, his lack of discernment and blind faith in

the assertions of commercial firms who have something to sell him are some of the greatest causes.

The remedy—it must be directed in two directions. The light of publicity must be cast on this nefarious practice, so that every physician, high and low, can see its details in the full glare of the limelight. And an influence must be exerted on the medical press to discontinue its fake and "patent medicine" advertising.

The better class of physicians in this country are the "doctors in charge of this case." The burden of responsibility rests with them.

PRELIMINARY STEPS IN THE INVESTIGATION OF GASTRIC FUNCTIONS.*

B. ONUF (ONUFROWICZ), M.D.

SONYEA, N. Y.

In making preparations for the investigation of the gastric functions of epileptics, particularly in idiopathic epilepsy, for which the Craig Colony for Epileptics seemed to offer a favorable field, worthy of careful and intelligent investigation, the fact appeared that the methods in vogue were not commensurate to scientific needs, as they do not offer that degree of exactness which would recognize beyond all doubt deviations from the normal, if such were not present in a very marked degree.

So many points have to be considered before conclusions regarding one special point can be made that if accuracy of method and analytic discrimination are not introduced in this field of research, results must necessarily be of such a vague character as not to allow any definite conclusions. This fact impressed the writer particularly in taking up the chemopathology of gastric secretion. It seemed absolutely necessary first to establish standards by means of which the components of the gastric juice could be quantitatively determined.

For the quantitative determination of the acids and acid salts of the gastric contents such standards have been established, but those used by the clinician at large are yet far from being unassailable.

So-called indicators are made use of for the quantitative discrimination, as one might say, of the different acidities. But anyone who studies the question a little, easily perceives how uncertain the discrimination thus obtained really is. To take an example: The quantitative determination of free hydrochloric acid is based on the fact that even slight concentrations of hydrochloric acid assume a dark pink color by the addition of one or two drops of dimethyl-amido-benzol, while solutions of organic acids, in order to produce the same color reaction, have to be present in such concentrations, as they are never found in gastric contents. Granting this to be the case, the problem might be simple enough if either free hydrochloric acid alone or organic acid (using this term in a comprehensive sense) alone were present. But in case of simultaneous presence of the two, the question naturally arises whether or not, and in what way, the organic acid may influence the reaction for the free hydrochloric acid.

Preliminary experiments have shown me that the organic acid undoubtedly does influence the reaction, if present in considerable quantity. It makes it much less definite, so that instead of a sudden reversal of color, taking place at the moment of neutralization, we ob-

tain a very gradual change of color which makes it impossible to define when neutralization has occurred. What will take place if only small quantities of the organic acids are present, and whether in such a case the result of titration by an alkali—with dimethyl-amido-azo-benzol as an indicator—will denote solely the acidity due to the free hydrochloric acid; or whether, on the contrary, it will indicate the sum of the acidities of the free hydrochloric and the organic acids. I have not investigated yet; but certainly this point needs elucidation and it is peculiar that more attention has not been paid to it.

Greater still are the difficulties to contend against when we attempt to determine the amount of pepsin present in the stomach contents. There are, to my knowledge, no chemical reactions by which this can be done, except by testing the digestive power of the gastric contents. We know, however, that the digestive faculty of pepsin unfolds itself only in the presence of hydrochloric or some other acid and that this acid must have a given concentration, varying for different foodstuffs, in order to develop the digestive power of the pepsin at its best.

Aside from others, three conditions, therefore, seem to be required for accurate tests:

1. A pepsin solution of standard strength for control tests.

2. Acidification of this pepsin solution by hydrochloric acid in definite proportion.

3. Bringing the hydrochloric acid percentage of the stomach contents under examination up or down to the same, or approximately the same, strength as that of the control mixture.

The control mixture of pepsin and hydrochloric acid must be made fresh before use, as the pepsin soon deteriorates in solution.

A further difficulty is that of always obtaining a pepsin of the same composition. This, I understand, is practically impossible, so that even the most reliable products or brands of this ferment are subject to some variation. Therefore the only way that seems open is to begin with a definite brand of pepsin, combine it with hydrochloric acid of definite strength, and test the digestive power of this control digestive fluid on albumin and eventually on casein, meat, gelatin and other foodstuffs. To do this successfully, i. e., to obtain reliable results, the foodstuffs mentioned will have to be standardized. One attribute of this standardization will have to be homogeneity of the foodstuff to be used as a standard. The white of an egg, for instance, shows such differences of density in its different parts that only a thorough redistribution would seem to make it fit for tests. The method I adopted for this purpose was to dry the white of an egg, pound it to a fine powder, redissolve it in distilled water, and either filter or centrifuge it. The latter process is quicker and more simple. After about five minutes' action of a water centrifuge, the redissolved white of egg is found to show three layers, one narrow upper foamy zone, one wide middle layer of clear fluid free of air bubbles, and a considerably less wide zone of sediment. Only the middle layer of clear fluid is used, by drawing it off with a pipette. Measurement of the volume of the unaltered, i. e., original, white of egg, and weighing of the same after drying, showed that the white of egg represents a solution of the dry albumin of about 12 per cent. strength. Such an artificial or disorganized white of egg of the same strength as the natural white of

* This article was prepared to be read before the Section on Pathology and Physiology of the American Medical Association at the Portland Session, July, 1905, but the author was unable to be present. It embodies work done at the Pathological Laboratory of the Craig Colony for Epileptics, Sonyea, N. Y.

egg, if prepared by using only the clear zone in the centrifuge fluid, showed some interesting physical qualities. On being coagulated by heat, it assumed a beautiful opalescence, being quite transparent in thin layers and of a jelly-like consistency. Of another peculiarity of such an albumin I shall have opportunity to speak later.

Having thus established a homogeneous test material as demonstrated for egg albumin, the next step is to test its relative quality by digestion tests. Practically the problem might be accomplished in the following manner: Note is taken of the particular "lot" of pepsin used for the control digestive fluid and also of the particular "lot" of albumin used in the control test. The first bottle of the dry pepsin used, be it an ounce or a quarter of a pound or another quantity, is called, Pepsin, Lot 1. A small amount of this is mixed with hydrochloric acid and water in the proportions found most suitable for the control digestive fluid. The digestive power of the latter is then tested on egg albumin Lot 1 dissolved in water in such or such percentage. By Dried White of Egg, Lot 1, is designated all the white of egg dried on a given date, say April 1, 1905, pulverized and well shaken, so as to give a uniform composition of the entire quantity dried at the time. The next lot prepared, say June 3, is designated as Dried White of Egg, Lot 2.

By testing pepsin, Lot 1, on white of egg, Lot 1, and then on white of egg, Lot 2, the following important result will be reached: 1. Either the digestive result is the same, i. e., the control digestive fluid prepared with pepsin, Lot 1, digests under equal conditions the same quantity of dried white of egg, Lot 2. This would be the most desirable outcome, as then the two lots of dried white of egg can be used indiscriminately for all digestion tests. 2. Or the digested quantities of the two white of egg lots are not the same. In the latter case the difference may be one of density only, or one of composition. If of composition, the problem would become a complicated one; but if, on the other hand, the difference was one of density only, the establishment of certain digestion laws may help us out.

If we study the effect of a given control digestive fluid, say on a 16 per cent. solution of dried white of egg and then again on solutions of the same white of egg but of a different percentage, the digestive effect obtained on these different concentrations ought to enable us to discover the laws which govern the digestive effect on the different concentrations of albumin; and the knowledge of such a law would, vice versa, enable us to infer the concentration of the dried white of egg from the digestive effect. In this manner, by mathematical calculation, the digestive effect of pepsin Lot 1 on white of egg Lot 2 could be substituted by the digestive effect of pepsin Lot 1 on white of egg Lot 1, or vice versa.

The next problem arising from this is a comparison of pepsin, Lots 2, 3, 4, etc., with pepsin Lot 1. This comparison has to occur through the intermediary of digestive tests on the white of egg lots; and proper interpretation of the ventual differences in the digestive powers of these various pepsins necessitates again the knowledge of physical laws. This certainly makes the problem a very complex one. But, as already mentioned, it is practically impossible to manufacture a pepsin of always uniform composition and digestive power. We have, therefore, practically no means of quantitatively determining the pepsin except by digestive tests, which again makes the study of the laws

above discussed very desirable, if not imperative. Encouraged by some results to be reported below, I intend taking up this study.

Our troubles, however, do not end here. In beginning digestion tests with pepsin on albumin, the selection of a reliable method presented itself. The choice finally fell on one promising the greatest accuracy. It was the method long in use by the school of Pawlow, and introduced, so far as I understand, by Dr. Mett, one of Pawlow's pupils. The principle of it is to fill glass tubes of an inner caliber of from 1 to 2 mm. with albumin from the white of egg and coagulating this albumin by heat. Tubes thus prepared, of a length of from 2 to 3 cm. or as much longer as may be desirable under given circumstances, are put into the digestive fluid to be tested and subjected to its action for ten hours at a temperature, preferably of 37 C. The length of the digested column is then read off by means of a scale.¹ The tubes are known under the name of Mett tubes, which name, for brevity, shall be made use of in this paper.

Pawlow's school was fully aware of the necessity of establishing the law governing the length of the digested column before the result of the tests could be utilized. It was, indeed, discovered by these authors and sounds as follows:²

The digestive powers of the juices tested are in direct proportion to the squares of the distances digested by them.

Pawlow and his pupils further found that the digestion of the albumin in the tubes progressed at a regular rate, so that the distance digested in the first hour in the incubator is just as long as that digested in the second hour, etc. This makes the method of the Mett tubes a very accurate one, if properly applied. The *sine qua non* conditions for its accurate workings are homogeneity of the albumin, absence of air bubbles, and even coagulation and close contact of the coagulated albumin with the wall of the tube.

The first two points offered considerable obstacles. The drying and pulverizing of the white of egg, however, removed the first obstacle, securing the desired homogeneity, while the centrifuge disposed of the second one—the air bubbles—very effectively in a few minutes, so that it became unnecessary to clear the dissolved albumin of air bubbles by standing, a method which, in view of the risk of decomposition, would be very objectionable. However, new gas bubbles may arise during the coagulation by heat from evaporation of the water of the albumin solution, if the heating is continued too long.

The third condition, even coagulation, is rather easily obtainable. Test tubes are stocked with empty Mett tubes 2 to 3 to 5 cm. long. Then the albumin is allowed to flow into the test tube while slanting the latter. Subsequently the test tube, firmly stoppered, is immersed in boiling water on a slight slant, preferably resting it on a layer of absorbent cotton so as to prevent too much heat communicating itself from the bottom. After the entire mass has turned opalescent white, it is good to leave it in for about a minute longer. By

1. I used the following means of measurement: A scale was drawn, the units of which were $\frac{1}{16}$ mm. This scale was photographed with a reduction to $\frac{1}{10}$. From the negative a positive was taken and the scale contained on the latter was covered with a microscope cover glass, fastened to it by means of xylodamar. The scale thus obtained had $\frac{1}{16}$ mm. for units, which, by means of a dissection microscope, could easily be read off. Indeed, even $\frac{1}{8}$ mm. could be measured.

2. If I have not rendered the exact wording of the law, I feel certain that the sense is as here given.

leaving it in too long, one risks the formation of steam bubbles by evaporation of the water of the albumin solution.

The fourth point, close contact of the coagulum to the tubes, may be obtained by washing and, of course, drying, the Mett tubes well before use. A shrinkage of the coagulum from the wall can thus be avoided with albumin solution of the strength of a natural white of egg. In using weaker concentrations a retraction was to be feared. My experience has been, however, that with all the concentrations that could be made to coagulate in one mass, no retraction took place. If, however, casein was used instead of white of egg, i. e., if milk was made to curdle by adding rennin, the coagulum formed retracted to a thin thread.

The next step is to cut the Mett tubes out, making the cuts as sharp as possible at the ends. They are then preserved in vaselin which, although somewhat disagreeable to handle, effectively prevents evaporation and apparently also decomposition of the albumin.

After obviating thus the difficulties enumerated, additional evidence of the reliability, i. e., homogeneity of the test material, can be obtained by placing the Mett tubes horizontally in the digestive fluid used for the test. If the coagulated albumin is homogeneous, the digestion will take place at both ends at exactly the same rate.

CONCENTRATION OF THE TEST MATERIAL TO BE DIGESTED.

Next in order of consideration is the concentration of the test material on which the digestive powers of the artificial control juice or actual juice are used. It has been mentioned that in the original, i. e., natural, white of egg, the albumin or albuminous substances are present in a solution about 12 per cent. strong. It would, therefore, seem most natural to conduct the digestion tests with a 12 per cent. solution of the dried white of egg. Indeed, Pawlow and his pupils, if I am rightly informed, have used the natural white of egg altogether. But we must not forget that their digestion tests were made with pure juice, as is the case in clinical tests. While, therefore, owing to the high concentration of the juice, the digested column in their experiments was long, reaching in some instances the length of $8\frac{1}{2}$ mm. in ten hours at body temperature, the figures obtained by myself with human gastric juice within twenty-four hours, also at body temperature, were 4 to 5 mm. only, or thereabouts. With such small figures it seemed hopeless to obtain accurate comparisons, and it seemed imperative to dilute the albumin to such a degree that the figures would be large enough to show deviations from the normal.

To what extent this may prove feasible, I can not say as yet. For the present, the fact is to be registered that an 8 per cent. concentration of the dried albumin can still be made to coagulate by heat, while a 6 per cent. solution remains liquid no matter how long heated; so that by this fact a limit is put to further successful dilution, if not otherwise modified. However, an 8 per cent. solution is so much more quickly digested than a 12 per cent. solution that the hope of its furnishing a test material complying with scientific requirements seems justified. But a proper utilization of the results of tests applied to the diluted 8 per cent. white of egg can be attained only by knowledge of the digestion law above mentioned, i. e., the law governing the digestion of different concentrations or densities of one and the same substance. The necessity of the knowledge of such a law applies also to other foodstuffs, such as starch, casein, gelatin, etc.

But, as already pointed out, casein, even if undiluted, does not fulfill the requirements of the successful application of the Mett tube method for digestion tests, since even in the undiluted milk the curdle formed by the action of rennin shrinks away from the wall of the Mett tube. Similarly starch, if in too weak concentration, does not solidify by heat; and in concentrations in which it is well solidified by heat, the digestion by saliva or even by strong diastase of malt, is so slow that one has again to contend with the objectionable feature of small figures which make it impossible to register slight deviations from the normal.

To obviate this obstacle, the idea occurred of distributing the test material over a carrier or vehicle, to which it is to be added in a liquid state, and then allow it to become solid by heat or other coagulating procedures—such as rennin for casein—allowing subsequently the carriers to become solid by cooling. The requirements that have to be put to such a vehicle are that it permit free penetration, that it be not digested, or very slowly digested, much slower than the test material carried by it, and that in such case the rate of its digestion be exactly known. The outcome of my study of the penetration laws thus necessitated is here given.

PENETRATION LAWS.

After having first selected a substance which seemed suitable for a vehicle, penetration experiments were first made with this substance without at first using it as a carrier for material that was to be digested. The choice fell on agar as a medium to be penetrated, but coagulated albumin was used also in the same rôle for some of the experiments. The penetrating fluid selected as a first choice was, naturally, hydrochloric acid, in view of its being a normal constituent of the gastric juice.

I shall first enumerate the laws so far established for the penetration of hydrochloric acid with relation to agar and then relate how they were found. To what extent they may prove applicable also to other penetrating substances and to other media to be penetrated, I am not prepared to say. But in a number of experiments the first-named law was found to hold true also for the penetration of hydrochloric acid (in solution of 2 per mille.) through homogeneous coagulated egg albumin.

1. The velocity of penetration is in direct proportion to the square of the distances penetrated. This law may eventually find its limitations by high or very low concentration of the acid, perhaps also of the agar. It so far was found to hold true for concentrations of from $\frac{1}{8}$ per mille. to 8 per mille. of hydrochloric acid and of from $\frac{1}{2}$ to 2 per cent. of the agar.

2. The concentration of the agar within the limits so far investigated has a relatively very slight influence on the velocity of penetration. A 2 per cent. agar is almost as quickly penetrated as a $\frac{1}{2}$ per cent. agar.

3. Within certain limits the square roots of the concentrations of the penetrating hydrochloric acid (also of other acids?) are in direct proportion to the squares of the distances penetrated by them in the same time. To concentrations above 3 or 4 per mille, and possibly below $\frac{1}{8}$ per mille, of the acid this law does not apply.

3. Very slight. In a former publication on "The Feasibility and Value of Accurate Methods in Clinical Investigations," Monthly *Cyclopedia of Practical Medicine*, vol. viii, p. 289, I had stated that the concentration of the agar within certain limits had no influence on the velocity of penetration. Further experiments with longer exposure, i. e., greater time periods, and correspondingly larger figures, have forced me slightly to modify the statement as above.

METHODS BY WHICH THE PENETRATION LAWS WERE ESTABLISHED.

It may be of some interest to give the evolution of the methods which led to the discovery of the laws above defined.

The fundamental fact had first to be established whether the fluids penetrated to any depth and in a reasonable time in the medium to be penetrated. For this purpose one of the reactions used for the determination of hydrochloric acid in gastric analysis was utilized, the dimethyl-amido-azo-benzol. Solutions of this compound, if made acid by hydrochloric acid, assume a deep pink color; if neutral or alkaline, a canary yellow, or (if stronger solutions of the dimethyl-amido-azo-benzol are used), orange color. The following experiment was first made:

A small grain of dimethyl-amido-azo-benzol powder was dipped into a thick celloidin solution and then fished out again with the celloidin surrounding it. This celloidin coating was allowed to dry, and the pearl thus formed was dipped into a weak solution of hydrochloric acid. The orange-colored coating at once turned pink. A new pearl was then made and inserted into a glass tube 3 cm. long and of an inner diameter of 2 mm. This glass tube was then put into a dish filled with 2 per cent. melted agar, allowing the latter to stream in, taking care to leave the pearl in position about the middle of the tube. Subsequently the agar was allowed to cool off until solid, and the glass tube was cut out of the solid agar mass and put into a solution of hydrochloric acid of about the concentration in which it is present in the normal gastric juice after an Ewald-Boas test meal, viz., approximately 2 per mille. After about an hour the hitherto orange-yellow coating of the pearl turned pink. The experiment was very instructive and convincing, but its inadequacy for finer measurements was apparent. It was therefore modified, as follows:

A few grains of dimethyl-amido-azo-benzol were dissolved in thick celloidin in a mortar, giving the celloidin an orange color. A glass rod was then dipped into this mass of molasses-like consistency, and by taking it out again, a celloidin thread was drawn. The rod was kept quiet until the thread was dry, and the latter was then severed off and cut into minute chips. These chips when put into hydrochloric acid solution gave the dimethyl-amido-azo-benzol reaction in a striking manner. The penetration experiment was now repeated. Instead of the pearl two chips were used, one being placed near the center of the agar-filled glass tube, the other about midway between it and the end. The reaction was seen to appear first in that part of the distal chip nearest the end of the tube. It was sharp enough to allow even after the second or third experiment the formulation of the law first enumerated, viz., that the velocity of penetration is proportionate to the square of the distances penetrated. But the figures were still somewhat too inaccurate; and the method had the great inconvenience that one had to sit right by and watch until the reaction appeared, and was unable to do anything else in the meantime. Moreover, the exact moment of the appearance of the reaction was hard to determine, as the transition from orange to pink was not sudden.

Another experiment was now made. Two drops of a 1 per cent. aqueous alizarine solution, as used for the determination of the total acidity minus combined hydrochloric acid in gastric analysis, were added to 10 c.c. of a melted $\frac{3}{4}$ per cent. agar solution, after the latter had been made slightly alkaline by five drops of

a 1/20 per cent. solution of sodium hydrate. The agar assumed now a purple color.

Glass tubes of an inner diameter of 2 mm. of different lengths were then placed in the agar solution, taking care to let them fill up without air bubbles. After the agar mass had become solid by cooling, the glass tubes were cut out of it. They were then placed in weak hydrochloric acid solution, the penetration of which showed very prettily by the transformation of purple into a yellow color at the ends. The yellow columns extended further and further toward the center, until after a certain time they met, the entire agar column having become yellow. The line of demarcation between the purple and yellow zones was very sharp, allowing measurements even of $\frac{1}{4}$ mm. by means of a scale (described in a former paragraph) divided into $\frac{1}{4}$ mm., which had been fixed photographically on a glass plate and was read off with a dissection microscope.

These alizarine agar tubes, one of which, under the action of about 2 per mille hydrochloric acid, is illustrated in Figure 1, made the experiment much easier and more accurate, and the conditions of the experiment were much more under the control of the experimenter. It was made possible to eliminate the influence of inequalities of the temperature by placing all tubes in the incubator, and maintaining an even temperature (37 C.) throughout the experiment. The tubes could be taken out after definite intervals and the distances penetrated measured. The more minutely all precautions were observed, the more closely did the actual

Fig. 1.—Illustrating an alizarine-agar tube under the action of hydrochloric acid approximately 2 per mille strong. It shows in the center the dark neutral zone, and at each end a pale acidified portion the length of which indicates how far the hydrochloric acid has penetrated. The color of the dark zone is purple, that of the pale portions yellow.

results agree with the results gained by calculation, thus confirming more and more strongly the law formulated. Here is an example:

First distance penetrated: 9 mm. Time required for penetration 120 minutes.
Second distance penetrated: 14 mm. Time required for penetration, 300 minutes.

In substituting x for the time required to penetrate the second distance (14 mm.), and calculating it according to the formulated law, this equation is obtained:

$$\begin{array}{l} \text{Square of 1st distance} \quad \text{Square of 2d distance} \quad \text{Penetration time for 1st distance} \quad \text{Penetration time for 2d distance} \\ (9 \text{ mm.})^2 : (14 \text{ mm.})^2 :: 120 \text{ minutes.} : x \\ x = \frac{14^2 \times 120}{9^2} = \frac{196 \times 120}{81} = 290 \text{ minutes.} \end{array}$$

In other words, the actual time was 300 minutes; the calculated time 290 minutes, i. e., an error no greater than 3 1-3 per cent.

Another instance:

$$\begin{array}{l} \text{Square of 1st distance} \quad \text{Square of 2d distance} \quad \text{Penetration time for 1st distance} \quad \text{Penetration time for 2d distance} \\ (5 \text{ mm.})^2 : (7 \text{ mm.})^2 :: 40 \text{ minutes.} : x \\ x = \frac{7^2 \times 40}{5^2} = \frac{49 \times 40}{25} = 39.2 \text{ minutes.} \end{array}$$

The actual time was 40 minutes; therefore, error for 40 minutes was $\frac{1}{5}$ of a minute, or 2 per cent.

To multiply these examples would be useless.

Here is an instance showing the validity of the second law, viz.: That within the limits so far investigated the concentration of the medium to be penetrated

has a relatively very slight influence on the velocity of penetration. The figures are given for both ends of the tubes, showing how closely the distances at each end tally with each other:

		Distance penetrated within 240 minutes by 8 per. mille hydrochloric acid.	
		At one end.	At the other end.
Through $\frac{1}{4}$	agar.27 mm.	.27½ mm.
Through $\frac{1}{2}$	agar.28½ mm.	.28½ mm.
Through $\frac{3}{4}$	agar.29½ mm.	.30½ mm.
Through $\frac{1}{4}$	agar.32 mm.	.32½ mm.
Through $\frac{3}{4}$	agar.35½ mm.	Not measured.

Previous experiments had been made by me with considerably shorter times of exposure to the acid, giving correspondingly smaller figures. This explains my former statement⁴ that the concentration of the agar has no influence on the velocity of penetration, in support of which statement, now slightly modified, the following figures had been adduced for the penetration of about 2 per mille hydrochloric acid:

		Distance penetrated within 20 minutes.	
		At one end.	At the other end.
Through $\frac{1}{4}$	agar.7½ mm.	.7½ mm.
Through $\frac{3}{4}$	agar.7½ mm.	.10½ mm.
Through $\frac{1}{2}$	agar.7½ mm.	.10½ mm.
Through $\frac{3}{4}$	agar.7½ mm.	.10½ mm.

This surprising second law will prove of practical value, as it will not be necessary to be very particular in the preparation of given concentrations of agar for carrier purposes.

Of great interest and eventual practical application is the third law: Within certain limits of concentrations which have been discussed in a former paragraph and which are the most important ones for gastric work; the square roots of the concentrations of the penetrating fluid are in direct proportion to the squares of the distances penetrated.

		Distance penetrated after 215 minutes.	
		At one end.	At the other end.
Fluid 1 = Hydrochloric acid approximately 2 per mille		.27½ mm.	.27½ mm.
Fluid 2 = 1/16 strength of Fluid 1.		.14 mm.	.14 mm.

Equation

Square root of concentration of Fluid 1.	Square root of concentration of Fluid 2.	Square of distance penetrated by Fluid 1.	Square of distance penetrated by Fluid 2.
$\sqrt{\frac{1}{16}}$	$\sqrt{\frac{1}{16}}$	x^2	$(.14 \text{ mm.})^2$
$1 : \frac{1}{4} = x^2 : .14^2$			
$x^2 = \frac{.14^2 \times 1}{\frac{1}{4}} = \frac{.196}{\frac{1}{4}} = .196 \times 4 = 784$			
$x = \sqrt{784} = 28$			

In other words, calculated penetrated distance = 28 mm.—real penetrated distance = 27½ mm., or an error of $\frac{1}{2}$ against 28, or of 1.8 per cent.

This third law, governing the velocity of penetration according to concentration, may find a practical application. The distance penetrated in a given time corresponds always to a definite concentration of a given acid (eventually also of other fluids). The method could therefore be used as a substitute of titration. To make it practical, a table could be compiled, giving for a given time, say two hours, on one side all the penetration distances from 0 to 50 mm.;⁵ on the other side the concentration of a given acid corresponding to these

distances. The limitation of the law may prove some obstacle to the successful working out of the method for acidities above 3 or 4 per mille, or below $\frac{1}{8}$ per mille. It seems, however, that even this obstacle may eventually be overcome.

For the determination of the free hydrochloric acid by this method congo red proved to be a very good indicator, giving a sharp line of demarcation and sharp contrast between the neutral red and the acidified blue portion. It is in this respect vastly superior to the di-methyl-amido-azo-benzol, in which the transition from the neutral yellow to the acidified pink portion is a gradual, hazy one. Congo red agar tubes have, unfortunately, one disadvantage, however, that of becoming deteriorated in a few days; the beautiful, clear red changes into a dirty brownish or reddish precipitate. The sharpness of the line of demarcation for the alizarine agar has already been pointed out. The alizarine agar tubes keep well for months.

As an indicator for total acidity, I have made a few experiments with phenolphthalein agar, and it seems to fill requirements well, giving a fairly sharp demarcation line, although not as sharp as the alizarine and Congo red.

Therefore, in view of the applicability of the phenolphthalein and alizarine tests, we have the means to determine by this method also the combined hydrochloric acid quantitatively, and it may eventually be entirely substituted for titration of the different acidities of the stomach. It would have the advantage over titration of taking much less time, since the agar tube for a given acidity needs no further manipulation than putting it into the gastric fluid to be tested and reading off the result, after it has been left in the incubator for the required period of time. The tedious process of anxious watching of the point of neutralization incident on titration is thus avoided and, furthermore, all three acidities can be read off at the same time, since a Congo-red, an alizarine and a phenolphthalein tube can be subjected to the test at the same time and read off at the same time.

Many of the details of this method still need working out and eventually modifying, and I reserve a more detailed account for a future publication.

The formulas which so far have given most satisfaction are:

Congo red tubes:	
1 per cent. aqueous solution of Congo red.	ggt. x
1 per cent. agar, hot, thoroughly liquid.	ad 311ss
Alizarine tubes:	
1 per cent. aqueous solution of alizarine.	ggt. 11
1 per cent. agar, hot, thoroughly liquid.	ad 311ss
1/10 per cent. aqueous sodium hydrate solution. ggt. 1-7	
i. e., until mixture has a purple color.	

As already mentioned, the Congo-red agar tubes keep only a few days, the alizarine tubes several months.

Before concluding this paper I wish to report on some interesting results of experiments made with 8 per cent. white of egg solution prepared in the manner described. This albumin solution was again filled into Mett tubes in the manner above described and coagulated in these by heat. The tubes were subsequently subjected at body temperature to an artificial gastric juice composed as follows:

Pepsin (Merck)	grs. 11
10 per cent. hydrochloric acid (this concentration was determined by titration)	1½ c.c.
Distilled water	5 c.c.

A narrow white disc was soon seen to appear near either end of the tube, respectively, moving gradually toward the middle of the tube, but not increasing in

4. Monthly Cyclopedia of Practical Medicine, vol. viii, p. 289; "The Feasibility and Value of Accurate Methods in Clinical Investigations."

5. Two per cent. hydrochloric acid $\frac{1}{2}$ c.c.; distilled water 5 c.c. Diluted with enough distilled water to make it 1/16 the strength of fluid 1.

7. For instance, in $\frac{1}{4}$ of a mm., i. e., $\frac{1}{4}$, $\frac{1}{2}$, $\frac{3}{4}$, 1, $1\frac{1}{4}$, $1\frac{1}{2}$, 1¾, 2 mm., etc.

its width, which was about $\frac{1}{4}$ mm. It is shown in a photographic reproduction in Figure 2, where it appears black instead of white. It was found that this zone moved with a velocity corresponding to law No. 1. After having reached the center and amalgamated with its opposite, it disappeared.

To find out to which of the constituents of the artificial juice this phenomenon was due, or whether it was due to both, the following experiment was made:

One tube was put into the artificial juice above described. Another tube was put into

Two per cent. hydrochloric acid $\frac{1}{2}$ c.c.
Distilled water $\frac{1}{2}$ c.c.

or, in other words, into the same fluid minus the pepsin.

Fig. 2.—Drawing reproduced from photograph of albumin tube, showing the demarcation line produced by the advancing hydrochloric acid. This line, while appearing white in the tube against the transparent other albumin, shows in the photograph as a dark line.

Both tubes were put into their respective fluids at the same time, and the effect was watched. It proved that both tubes showed the disc, and that it moved with exactly the same velocity in both, showing thus that this demarcation line was purely due to the influence of the hydrochloric acid, since I may add that distilled water alone did not produce such a line.

Here are the figures illustrating the results:

Experiment with the fluid containing the hydrochloric acid plus pepsin.		Experiment with the fluid containing the hydrochloric acid alone.	
At one end.	At the other end.	At one end.	At the other end.
1. After 31 minutes... 2% mm.	2% mm.	2½ mm.	2% mm.
2. After 62 minutes... 3% mm.	3% mm.	3½ mm.	3% mm.
3. After 124 minutes... 5% mm.	5% mm.	5½ mm.	5% mm.

In testing here again the validity of the first penetration law by calculating the penetration time of distance $5\frac{3}{8}$ mm. from penetration time 62 minutes and penetration distance of $3\frac{3}{4}$ mm., the following result is obtained:

Square of 2d distance penetrated. (3¾ mm.)² :	Square of 3d distance penetrated. (5⅜ mm.)² :	Penetration time for 2d distance, 62 minutes.	Penetration time for 3d distance, x
---	---	---	-------------------------------------

$$x = \frac{(5\frac{3}{8})^2 \times 62}{(3\frac{3}{4})^2} = \frac{28,896 \times 62}{14.06} = \frac{1791.18}{14.06} = 127 \text{ minutes.}$$

Instead of 124 minutes actual time. Error 3 or 127, or 2.8.

To what use the observations just reported may be put it is difficult to say, although there seems a prospect of utilizing them for establishing landmarks in the digestion tests.

In conclusion, I take occasion to correct a statement made by me in a contribution treating partly on the same subject and published in the *Monthly Cyclopedia of Practical Medicine*, vol. viii, p. 289, in the form of an editorial bearing the title: "The Feasibility and Value of Accurate Methods in Clinical Investigations." The statement referred to was the one that coagulated disorganized egg albumin is digested not only by pepsin plus hydrochloric acid, but even by hydrochloric acid alone of 2 per mille strength. Control experiments have made it very probable, if not certain, that this statement was wrong, evidently the result of some error of labeling. I corrected it in the proof of said editorial, but the proof reached the publishers so late that this and some other corrections could not be inserted.

PNEUMONIA.*

W. J. GALBRAITH, A.M., M.D.

Chief Surgeon Cananea Consolidated Copper Company, Cananea, Sonora, and the Green Gold Silver Company, Chihuahua.

CANANEA, SONORA, MEXICO.

A generous experience in the management of pneumonia during the last two years has given me an opportunity to offer some suggestions concerning its treatment that merit consideration. As my efforts and success in the treatment of this disease are based on my personal observations, many statements may appear dogmatic. My object is to give a synopsis of the details and indications that should be observed in applying my method of treatment rather than any speculative or theoretic views that would occasion a new engagement on the old battle ground of medicine.

Pneumonia is a septic febrile disease characterized by an early inflammatory attack on the lung tissue and frequently followed (by the actions of its toxins) by complications that mechanically interfere with the function of the heart and chemically change the condition of the blood to such an extent that even those who are fortified by unusual vigor frequently perish. Its etiology is the presence or absorption of pyogenic germs, whose rapid development is produced by a propagating bed due to the influence of a sudden reduction in surface temperature, in which reduction alcohol, cold and wet weather are frequent factors.

To my mind, the prevalence of pneumonia and its increasing mortality brand it as one of the foremost diseases for our professional consideration. While differing from nearly every writer on pneumonia, I do not wish it understood that I look on their efforts as unavailing, as I fully appreciate their honorable efforts in lending valuable aid in divers ways. I must, however, take issue with those who recommend expectant measures as the principle of treatment, and state that physicians are powerless to modify or to lessen the course of this formidable disease by any therapeutic agent.

In my treatment the antitoxin effect is first noticed in the pulse. If the treatment is properly administered, a favorable circulation can invariably be maintained throughout the convalescing period. Following the improvement in the pulse, the temperature begins to drop; respiration improves, as well as the cyanotic condition which is frequently noticed, especially in neglected cases, in which alcoholic stimulation has masked the invasion of the pneumonic process by its anesthetic influence. Dr. Charles F. Neider,¹ of Geneva, N. Y., mentions what I have so frequently demonstrated, in the following quotation: "Instead of a high-tension pulse, which is usually present in pneumonia, the pulse was of nearly normal tension and of good value. When there was cyanosis, it was promptly relieved."

I am satisfied that our continued, as well as our primary efforts, should be directed to applying measures that will fortify the heart and destroy micro-organisms and their products that produce sepsis. To treat pneumonia as a localized inflammation or as a functional disturbance, without considering the dangerous sequelae that are sure to follow, is about as rational and logical as it is to advise expectant measures. The keynote and foundation of the principles that commend my treatment is the fact that it prevents the manifestation of

* With the exception of the valuable clinical reports of Drs. Gustetter, Carpenter, Butzow, Hanev and Dudley, the basis of this article consists of extracts from a lecture recently delivered at the New York Polytechnic by request of Professor Beal.

1. THE JOURNAL A. M. A., Nov. 18, 1905.

septicæmia. The success which I have obtained by having the courage of my convictions, in what may be looked on as a formidable practice, was not without its anxious hours, and well can I appreciate a physician's anxiety after he has given the first sixty- or seventy-grain dose of quinin; but if there is a medicine in existence that will secure specific results I believe that it is quinin and iron properly administered in pneumonia. No medicine or antitoxin, in my experience or observation, has secured the phenomenal results that I have had in the treatment of pneumonia. I consider the use of stimulants (alcohol, strychnin, etc.) during the active stage of pneumonia not only contraindicated, but dangerous. By increasing the heart's action during its overtaxed period, when handicapped by the toxic condition of the blood that it is to distribute, the mechanical conditions that are distressing the patient are increased.

I earnestly solicit an honorable expression from those who choose to practice my method. Scores of physicians throughout the country have suggested the possibility of so many etiologic factors that I accept this opportunity of answering the many inquiries by simply stating that the etiology in this locality is no doubt the same as elsewhere and we have the same typical lobar pneumonia. Those who are not acquainted with the pneumonia that is found in all high altitudes we envy for the mildness of their cases. A careful review of the clinical reports which my colleagues have herewith submitted substantiates my claim that quinin will not depress the heart during the active stage of pneumonia; on the contrary, it is the most reliable stimulant and produces the effect that we have looked for in other remedies in vain.

Quinin, as I administer it, will not only reduce the frequency of the heart, but will increase its volume and the peripheral circulation as well. To prove its indication, I can positively state that in not a single instance in which large doses have been administered during the active stage of the disease has cinchonism been observed. With the exception of a slight ringing in the ears in two or three cases only, not an unfavorable symptom has ever been reported from its direct or remote influence.

From a scientific standpoint, I regard the achievement in preventing pneumonic cardiectasis, commonly called crisis, with greater favor than I do the recovery. Moreover, what proof (outside of a personal experience) is lacking to prove that my method of treating pneumonia is worthy of consideration? Compare the reports of my colleagues, who have treated cases according to my method, with the reports of those who have adopted the expectant plan. Note the absence of those alarming conditions that occur with due regularity during the sixth, seventh and eighth days of the disease. Note the absence of pain and the comfort the patient experiences within twenty-four hours after the initial dose of quinin and iron. So seldom do my patients complain of pain that I am safe in stating that I have not administered any anodyne for nervousness or pain, except in three or four out of the last hundred cases. Note the reduction of mortality from 75 per cent. to less than 2 per cent. Note the early resolution and infrequent complications.

Do not for an instant entertain the belief that I have overdrawn my picture, for the former mortality in the great majority of my cases fully justifies my remarks to say nothing of the terrible suffering and the alarming symptoms that preceded dissolution.

It may be thought that I am using an argument that will prompt physicians to accept my views against their

own judgment; but I agree that that is my object, provided that my advice is followed and that the details of the treatment are observed as minutely and carefully as the surgeon prepares his patient and himself for a modern aseptic operation. Pneumonia, according to my mind, comes as near being a disease for a surgeon's advice and counsel as any disease classified under a medical head. The surgeon who simply adds a little carbolic acid or bichlorid of mercury to a basin of water and washes his hands before operating is as unfair to his patient as the man who, from timidity and fear, subdivides the doses that I have recommended to be given and reports his cases, whether successes or failures, as being treated by my method.

It is quite true that quinin acts as the principal factor in pneumonia, but iron also is of the utmost importance. For nearly seventy-five years the physiologic action of quinin has interested the medical profession as has that of no other remedy, and we are still unable to state from a positive knowledge its true value.

I take great pleasure in submitting the clinical reports of Dr. A. L. Gustetter, acting assistant surgeon United States Public Health and Marine-Hospital Service, Nogales, Ariz., and Drs. E. M. Carpenter, T. F. Butzow, W. P. Hancey and H. D. Dudley, of Cananea, Mex., to whom I extend my sincere thanks for the many valuable suggestions they have offered from time to time.

CASE REPORTS BY DR. A. L. GUSTETTER.

CASE 1.—*Patient*.—A. L., aged 55, Mexican, weight 210 pounds, married, with a very pronounced alcoholic history, was first seen March 24, when he walked into my office for medical advice.

Examination.—His temperature was 104; pulse, 120; respiration, 30. He was just recovering from a severe chill and complained of great pain in the left chest. I found a pneumonia involving the left lower lobe.

Treatment.—He was instructed to return to his home and to go to bed. He was given fifteen drops of saturated solution of potassium iodid, increasing two drops every two hours, until thirty-one drops had been given, when he was instructed to begin again with fifteen drops and repeat the same method of increasing the dose. His temperature was reduced to 102 and remained there almost constantly until March 27, the fourth day of his illness, when the following changes occurred:

Course of the Disease.—March 27: At 2:15 p. m. temperature was 104.4; pulse, 120; respiration, 31. There was pain in the right chest; also pain and tenderness in the region of the gall bladder and involvement of the lower lobe of right lung. Dr. W. J. Galbraith of Cananea, Mexico, was visiting in Nogales at the time and I invited him to see the case in consultation. Forty grains of quinin were administered, as a result of our consultation, and one hour later thirty-five grains more were given. At 5:30 p. m., three hours and fifteen minutes later, his temperature was 104; pulse, 114; respiration, 28. Twenty grains of quinin were given with the direction to administer fifteen drops of tincture of chlorid of iron every three hours. At 8:15 p. m. temperature was 102.8; pulse, 114; respiration, 23. At 11:15 p. m. temperature was 101; pulse, 110; respiration, 28; profuse perspiration. Patient said he felt fine and even on direct questioning made no complaint of ringing in the ears.

March 28: At 8:45 a. m. temperature was 101; pulse, 100; complained of slight deafness. Ten grains of quinin were ordered every three hours. At 11:45 a. m. temperature was 101.6; pulse, 98; respiration, 34. He had no difficulty in hearing, nor had he any ringing in the ears. At 2:45 p. m. temperature was 102.2; pulse, 108; respiration, 35. He was very uneasy. At 5:45 p. m. temperature was 101.4; pulse, 98; respiration, 29. Microscopic examination of urine showed the presence of granular casts. At 8 p. m. temperature was 101.6; pulse, 98; respiration, 36; the patient was slightly delirious.

March 29: At 6 a. m. temperature was 101.6; pulse, 98; respiration, 36; patient rested fairly well the previous night.

At 9:15 a. m. temperature was 101.8; pulse, 104; respiration, 35. Five grains of quinin were ordered and the iron was continued every three hours. At 12:15 p. m. temperature was 102.4; pulse, 108; respiration, 36. At 3:30 p. m. temperature was 103.2; pulse, 110; respiration, 36; 10 grains of quinin were administered. At 5:15 p. m. temperature was 103; pulse, 110; respiration, 36. Patient was delirious; 15 grains of quinin were given. At 8 p. m. temperature was 102.4; pulse, 118; respiration, 37; in his delirium patient got out of bed.

March 30: Temperature was 99.8; pulse, 100; respiration, 33. The quinin was suspended and the iron continued at irregular intervals on account of delirium. At 4:15 p. m. temperature was 101; pulse, 103; respiration, 34. The patient regained consciousness. Thirty grains of sodium bromid and 10 grains of chloral were ordered given at 8:30 p. m.

March 31: At 9:45 a. m. temperature was 99.6; pulse, 112; respiration, 36; the patient slept well all night and said he felt fine.

April 1: Sixth day of treatment. Temperature was 99; pulse, 88; respiration, 26. Patient was allowed to sit up in bed; he said he felt fine and had slept all night. He had a good appetite.

April 2: Patient was discharged without any remaining symptoms. Temperature, pulse and respiration were normal. Microscopic examination of urine showed presence of very few hyaline casts.

Remarks.—This case is interesting because of the age of the patient, obesity, the fact that he was an alcoholic subject and the delirium.

CASE 2.—*Patient.*—C. C., widow, aged 65, obese, asthmatic.

Examination.—April 1, 9 a. m.: Temperature, 100; pulse, 90; respiration, 26. The patient complained of pain in the left chest and of cough. Physical examination of lungs was negative.

Treatment.—I decided to watch the case, suspecting it to be one of beginning pneumonia. At 8 p. m. temperature was 103.2; pulse, 100; respiration, 32. Patient was spitting blood, breathing was labored and very painful. Owing to her age and weakened physical condition, only 20 grains of quinin were given. At 5 p. m. temperature was 103.6; pulse, 106; respiration, 44. Twenty grains of quinin were given and 15 minims of tincture of iron were ordered given every three hours.

April 2: At 8:55 a. m. temperature was 99; pulse, 70; respiration, 28; quality of pulse better than before her illness. Patient had all the physical signs and symptoms of pneumonia, involving the lower left lobe.

April 3: At 9:30 a. m. temperature was 102; pulse, 76; respiration, 25. Felt fine. Ten grains of quinin given every three hours. At 5:30 p. m. temperature was 100.8; pulse, 72; respiration, 30. Dose of quinin reduced to 5 grains every 4 hours. The iron was continued. Sodium bromid and chloral were ordered given at 8:30 p. m.

April 4: Temperature was 99; pulse, 70; respiration, 28. Patient sat up in bed.

April 5: At 9:30 a. m. temperature was 98.6; pulse, 62; respiration, 24. Coughing had ceased; sputum was clear, and the patient sat up in a chair.

April 6: Sixth day of disease. Temperature, pulse and respiration were normal. The patient walked about the house, and was discharged without any remaining symptoms. This patient never suffered any delirium or complained of ringing in the ears.

CASE 3.—*Patient.*—E. T., aged 29, Mexican, miner.

Examination.—May 23, at 9 a. m., temperature was 104.8; pulse, 130; respiration, 50. The man complained of sharp pain in the right chest. He had suffered with a severe chill the night previous. Physical examination showed pneumonia, involving lower lobe of right lung, with annoying cough.

Treatment. I gave 30 grains of quinin. May 23, at 10 a. m., temperature was 104.8; pulse, 140; respiration, 54; 30 grains of quinin were given and 15 drops of iron ordered every 2 hours. At 12:30 p. m. temperature was 103; pulse, 130; respiration, 50. There was profuse perspiration. At

3:30 p. m. temperature was 102.4; pulse, 110; respiration, 44. Patient was still perspiring; he did not complain of deafness or ringing in the ears. Ten grains of quinin were ordered and the iron was continued. At 6 p. m. temperature was 102; pulse, 106; respiration, 40.

May 24: At 9 a. m. temperature was 102.4; pulse, 110; respiration, 44. There was bloody expectoration. At 12:30 p. m. temperature was 101.6; pulse, 108; respiration, 40. Sodium bromid and chloral were ordered at 8:30 p. m.

May 25: At 9 a. m. temperature was 100; pulse, 94; respiration, 36; patient resting very well. Ten minims of iron were ordered given every 3 hours. At 4 p. m. temperature was 101; pulse, 90; respiration, 40. Sputum was rusty. The amount of quinin was reduced to 5 grains every 3 hours.

May 26: At 9 a. m. temperature was 100.2; pulse, 90; respiration, 34; patient was resting well. At 4 p. m. temperature was 102; pulse, 100; respiration, 40; patient did not feel so well.

May 27: At 8:30 a. m. temperature was 103.6; pulse, 110; respiration, 50. He complained of pain in the left chest. Examination showed involvement of middle and lower lobes of left lung. Thirty-five grains of quinin were administered and 10 drops of iron were ordered given every 2 hours. At 9:30 a. m. temperature was 104; pulse, 120; respiration, 48. Thirty-five grains of quinin were given. At 2 p. m. temperature was 102.4; pulse, 108; respiration, 38. There was profuse perspiration. At 6:30 p. m. temperature was 102; pulse, 100; respiration, 40; 15 grains of quinin were ordered given every 3 hours, and the iron was continued.

May 28: At 9 a. m. temperature was 101; pulse, 90; respiration, 36. Patient felt much better. At 4 p. m. temperature was 100; pulse, 94; respiration, 40.

May 29: At 9 a. m. temperature was 99; pulse, 98; respiration, 34.

May 30: At 9 a. m. temperature was 100; pulse, 90; respiration, 36. The amount of quinin was reduced to 5 grains every 3 hours, and the iron was continued. At 6 p. m. temperature was 99.8; pulse, 90; respiration, 32.

May 31: At 8:30 a. m. temperature was 99.6; pulse, 90; respiration, 34. Medicines discontinued; the patient felt fine, and his appetite was good.

June 2: Temperature, pulse and respiration were normal. He was able to sit up in a chair.

June 3: Discharged.

CASE 4.—*Patient.*—A. M., male, aged 14.

Examination.—June 4, 9 a. m., temperature, 103; pulse, 130; respiration, 30. Patient complained of severe pain in right chest, with frequent coughing.

A diagnosis was made of pneumonia, involving the lower lobe of the right lung.

Treatment.—At 10 a. m., June 4, I administered 30 grains of quinin. At 11:30 a. m. temperature was 104; pulse, 134; respiration, 44. Twenty grains of quinin and 10 minims of tincture of iron were administered every 4 hours. At 4 p. m. temperature was 102.6; pulse, 120; respiration, 52. The patient was expectorating rusty-colored sputum and perspiring freely. Five grains of quinin were ordered given every 3 hours.

June 5: At 8:30 a. m. temperature was 101; pulse, 118; respiration, 40. The patient was coughing but little and the treatment was continued. At 4 p. m. temperature was 100; pulse, 108; respiration, 40.

June 6: At 9 a. m. temperature was 100.4; pulse, 110; respiration, 34. The patient had rested well the previous night; he had no pain and very little cough. At 5:30 p. m. temperature was 99.8; pulse, 100; respiration, 28. Quinin was discontinued; 10 drops of iron were given every 4 hours.

June 8: At 9:30 a. m. temperature was 99.4; pulse, 104; respiration, 26. Patient was allowed to sit up in bed one hour in the morning and again one hour in the afternoon.

June 9: Temperature was 98.8; pulse, 94; respiration, 22. The patient was able to sit up in a chair. He had a good appetite, and said he felt fine.

June 10: Seventh day after beginning treatment and eighth day of disease. Patient was discharged with normal temperature, pulse, and respiration.

CASE 5.—Patient.—Miss M., aged 22, American. On my first visit, November 8, I found that, on November 4, the patient had suffered with a severe chill. She complained of pain in the lower part of the right chest, with annoying cough. The sputum was blood-tinged.

Examination.—Temperature was 104.6; pulse, 130; respiration, 50. There was severe pain over the entire right chest; breathing was labored, and expectoration bloody.

Diagnosis.—Pneumonia, involving middle and lower lobe of right lung.

Treatment.—I administered 45 grains of quinin as the initial dose. At 9 p. m. 50 grains more were administered and 15 minims of tincture of iron were ordered given every 2 hours.

November 9: At 7:30 a. m. temperature was 101; pulse, 100; respiration, 36. At 2:30 p. m. temperature was 100; pulse, 106; respiration, 34. At 8:30 p. m. temperature was 100.4; pulse, 110; respiration, 40.

November 10: At 8 a. m. temperature was 99.4; pulse, 90; respiration, 30. Patient able to sit up in bed. Iron continued. At 6 p. m. temperature was 99; pulse, 78; respiration, 32.

November 11: At 8:30 a. m. temperature was 98.4; pulse, 82; respiration, 24. Patient sitting up in chair; had a good appetite and felt comfortable.

November 12: At 9:30 a. m. temperature, pulse and respiration normal. Patient discharged.

Remarks.—My experience in the treatment of pneumonia with quinin and iron comprises 13 cases. All of these terminated in successful recoveries, as against the previous mortality which held forth in Nogales and vicinity, of about one recovery out of five cases treated by other therapeutic measures. I have had ample opportunity in this section of the country to try all, or nearly all, of the most approved remedies in the treatment of pneumonia, but I have always felt that, if the patient recovered, it was in spite of the medicines that were used. The other cases which I have not cited all went on to recovery in much the same time and manner.

From my most recent experience with the quinin treatment, I feel satisfied that, if it were continued in fairly large doses until the temperature dropped to normal, involvement of the other lobes of the same lung or of the healthy lung would not occur. I believe the question of how much quinin should be administered must depend on the severity of the general symptoms, age and especially the length of time the disease has progressed before the treatment is begun. In my experience with children, I have observed that they stand proportionately large doses as well as adults.

I am frank to confess that I felt considerable timidity when I administered the first large doses, but the immediate relief which the remedy afforded overcame my hesitancy. My experience with Dr. Galbraith's treatment has convinced me that we have in quinin and iron a specific for pneumonia.

CASE REPORTS BY DR. T. F. BUTZOW.

CASE 1.—Patient.—J. H., aged 42, saloonkeeper.

History.—The patient was a hard drinker and was just recovering from a two weeks' debauch. On the night of November 6 he had a chill and drank over a quart of whisky, thinking it might warm him up.

Examination.—Temperature, 105.5; pulse, 140; respiration, 46. He complained of pain in the lower lobe of the right lung, with consolidation.

Diagnosis.—Lobar pneumonia.

Treatment.—Fifty grains of quinin were administered at 10 p. m., followed one hour later by 25 grains.

November 7: At 11 a. m. temperature was 103.4; pulse, 118; respiration, 30. Quinin, 50 grains, was administered and tincture of iron, 15 minims, was ordered every 3 hours. At 8 p. m. temperature was 101.8; pulse, 100; respiration, 22. At 10 p. m. 40 grains of quinin were given, and at 11 p. m. 20 grains more. The iron was continued.

November 8: At 11 a. m. temperature was 99; pulse, 80; respiration, 20. Sputum was bloody. At 8 p. m. temperature was 101; pulse, 84; respiration, 20. At 10 p. m. 40 grains of quinin were administered, followed one hour later by 20 grains; the iron was continued.

November 9: At 11 a. m. temperature was 98; pulse, 80; respiration, 20. At 8 p. m. temperature was 99; pulse, 80; respiration, 19; 20 grains of quinin were administered.

November 10: At 11 a. m. temperature was 97.2; pulse, 76; respirations, 19. At 8 p. m. temperature was 99; pulse, 76; respiration, 19.

November 11: At 11 a. m. temperature was 97; pulse, 74; respiration, 18. At 8 p. m. temperature was 99; pulse, 76; respiration, 19; 15 grains of quinin were administered.

November 12: At 11 a. m. temperature was 97; pulse, 70; respiration, 18. At 8 p. m. temperature was 97; pulse, 56; respiration, 18.

November 13: At 11 a. m. temperature, pulse, and respiration were normal. Patient was discharged and placed on small doses of iron and quinin as a tonic.

CASE 2.—Patient.—Mexican, male, aged 43, smelterman.

History.—This man was a mescal (Mexican whisky) suspect. His wife said he had been on a drunk for about a week, and that he came home on the morning of November 20 complaining of pain over his entire chest.

Examination.—November 20, 11 a. m., he complained of severe pain over the region of the gall bladder, and was expectorating bloody sputum. The lower right lobe was consolidated. Temperature was 103.6; respiration, 46; pulse, 148.

Diagnosis.—Lobar pneumonia.

Treatment.—Fifty grains of quinin were given at 11 a. m. and 25 grains one hour later. At 8 p. m. temperature was 104; respiration, 38; pulse, 120; 40 grains of quinin were administered and 25 grains one hour later.

November 21: At 11 a. m. temperature was 102.4; respiration, 30, and pulse, 109. Thirty grains of quinin were administered. At 8 p. m. temperature was 102; pulse, 118; respiration, 36; 50 grains of quinin were administered and 25 more one hour later.

November 22: At 11 a. m. temperature was 99; respiration, 26; pulse, 98. Fifteen minims of iron were ordered given every 3 hours.

November 23: At 11 a. m. temperature was 98.6; respiration, 99; pulse, 87. The iron was continued. At 8 p. m. temperature was 100; pulse, 91; respiration, 23. Thirty-five grains of quinin were ordered and 15 grains more one hour later.

November 24: At 11 a. m. temperature was 99.2; respiration, 20; pulse, 90. The iron was continued. At 8 p. m. temperature was 102; respiration, 24; pulse, 100. Forty grains of quinin were administered and 20 grains more one hour later.

November 25: At 11 a. m. temperature was 98.2; respiration, 19; pulse, 97. The iron was continued.

November 26: At 11 a. m. temperature was 97; respiration, 19; pulse, 74.

November 27: At 11 a. m. temperature was 96.8; respiration, 18; pulse, 68. The iron was continued. Patient was discharged, November 27, with normal temperature, pulse, and respiration. Tonic doses of iron and quinin were ordered 3 times a day for one week.

CASE 3.—Patient.—F. F., Mexican, aged 35, miner.

History.—The patient had a severe chill, with pain on the right side, on evening of November 19. He had been on a ten days' drunk and gave a history of being a periodical drunkard.

Examination.—There was pain and tenderness in the region of the gall bladder and the lower lobe of the right lung. Respiration was labored, and the sputum bloody.

Diagnosis.—Pneumonia, involving right lower lobe.

Treatment.—November 20, 10 a. m., temperature was 103.8; pulse, 108; respiration, 40. Fifty grains of quinin were administered and 25 grains more one hour later. At 3 p. m. temperature was 97; pulse, 92; respiration, 28. At 7 p. m. temperature was 100; pulse, 80; respiration, 28; 20 grains of quinin administered.

November 21: At 7 a. m. temperature was 102; pulse, 75; respiration, 33. Twenty-five grains of quinin were administered and 15 grains more one hour later. At 7 p. m. temperature was 103; pulse, 80; respiration, 28. Forty grains of quinin were administered and 20 grains more one hour later; iron was also given.

2. Compare the record of Dr. Gustetter's first two cases with the treatment of his last three.

November 22: At 7 a. m. temperature was 99; pulse, 70; respiration, 24.

November 23: Temperature was 97.2; pulse, 60; respiration, 28. At 7 p. m. temperature was 99; pulse, 65; respiration, 24. Twenty grains of quinin were administered.

November 24: Temperature was 98; pulse, 60; respiration, 25.

November 25: At 7 a. m. temperature was 98; pulse, 65; respiration normal.

November 26 and 27: Temperature and pulse remained normal.

November 28: The patient was discharged, with normal temperature and pulse. Tonic doses of quinin and iron were ordered 3 times a day during the last 3 days, to be continued 4 days more.

Remarks.—I wish to call attention to the fact that in my experience quinin and iron, when given as recommended by Dr. Galbraith, act practically as specifics in pneumonia. It is my experience that alcoholic subjects respond to the treatment more readily than do non-alcoholic patients. The effects of quinin on the circulation can not be questioned. In every case the same results are obtained, namely, a normal tension and good volume of pulse within twenty hours from the initial dose. The severe pain complained of is not only relieved, but prevented and seldom does it become a factor of any importance from the beginning of the treatment until the patient is well. In all my cases I continue tonic doses of quinin and iron at least one week after the patient is discharged.

CASE REPORTS BY DR. H. D. DUDLEY.

CASE 1.—*Patient.*—J. L., male, aged 32; nationality, Mexican; miner.

Family History.—Negative.

Personal History.—The patient has never been sick since childhood. He is robust and well developed; he smokes and uses spirits. There was no specific history. He was taken ill May 20, about 6 p. m., with a severe chill lasting for about one hour, followed by headache and pain in his bones. During the night he began to have pain in his left side and was kept awake by coughing.

Second day: Cough and pain both increased in severity. During the afternoon he began to expectorate blood-stained sputum. He had great thirst and was very hot; he vomited twice during the day and was delirious at times during the night.

Examination.—I first saw the patient at 10 a. m. on the third day of the disease. I found him with a temperature of 105; pulse, 140; respirations very superficial and a general toxic appearance. Percussion revealed an absolute dullness extending from supraclavicular region over the entire lung area on left side and front area of precordia; dullness obliterated. Auscultation showed bronchial breathing at apex; some crepitant râles lower down in front and posteriorly a distinct pleuritic rub.

Treatment.—Fifty grains of quinin sulphate were given at once, followed in 2 hours by 20 more. About 30 minutes after taking second dose the patient vomited. At 3:30 p. m. temperature was 101.2; pulse, 140; 20 grains of quinin were administered. A calomel purge, followed by a saline in 6 hours, was ordered given that evening. The cough and pain continued during the night, and the patient became delirious.

Fourth day: At 5 a. m. I received a hurried call by messenger, who stated that the patient was dying. On arrival, I found his temperature 102; pulse, 120. Thirty grains of quinin were ordered. At 4 p. m. temperature was 104; pulse, 100. The patient had a copious bowel movement, and there was profuse perspiration, with little cough and no expectoration.

Fifth day: At 11 a. m. temperature was 98; pulse, 100. There was slight cough and no pain in chest on forced inspiration. An expectorant cough mixture was ordered. At no time were there any symptoms of cinchonism.

CASE 2. *Patient.*—B. V., aged 24, Mexican, miner. (History unobtainable.)

History.—On November 1, patient complained of headache, with slight cough and pains in back and the legs. On November 2, he had a chill, followed by fever and pain over the right thoracic region.

November 3: I first saw the patient at 4:30 p. m.; temperature was 103.5; pulse, 88; rapid, shallow respiration; increased vocal fremitus; tubular breathing, and pronounced dullness over the right upper lobe. Patient refused treatment, and no medicine was taken that day or night.

November 4: Temperature was 104.5; pulse, 120. Quinin, 50 grains, was administered and followed in 2 hours by 30 grains more. Ten grains every 2 hours were ordered given during the night.

November 5: Temperature, 99; pulse, 80. The patient was coughing a little, but had no pain; he was nauseated. I gave 5 grains of chlorotone, followed in one hour by 30 grains of quinin.

November 6, 7, 8 and 9: Temperature and pulse remained normal. The recovery was uneventful.

Remarks.—The specific effects of the treatment of pneumonia with quinin and iron in those cases in which I have used it are very gratifying. However, I find great difficulty in using this or any other treatment among the people of my district.

CASE REPORTS BY DR. W. P. HANEY.

CASE 1.—*Patient.*—Mrs. P., aged 30, Mexican, mother of three children, about seven months pregnant, was suddenly taken with chill, followed by pain in right side, fever, and bloody sputum.

Examination.—I saw her on the first day of her illness about 4 p. m. Temperature was 104; pulse, 120, and respirations rapid. She complained of severe pain in the region of the right side. There was dullness over the right lower lobe, with slight consolidation.

Treatment.—Fifty grains of quinin were administered and 10 minims of tincture of chlorid of iron were ordered given every 4 hours.

Second day: Temperature was 100; pulse, 96; sputum clear. Twenty grains of quinin were administered and the iron was continued.

Third day: Temperature was slightly subnormal; pulse, 74. She had no pain and respiration was easy. There was slight mucopurulent expectoration. Quinin in small doses and an expectorant mixture were ordered and continued until the sixth day, at which time the patient was discharged from treatment.

CASE 2.—*Patient.*—M. F., aged 36, Mexican, miner.

History.—The patient stated that he was taken ill three days before, about 4 in the morning, shortly after returning from his work in the mines. He had a severe chill at the time, lasting about 40 minutes, followed by severe pain in left side, and later in the day he began to spit blood. He was treated by home remedies for the first three days, but grew steadily worse, and on the morning of October 12 I was called to see him.

Examination.—I found him with a temperature of 103.8; pulse, 140, and respiration, 48, very shallow, and with a pronounced expiratory grunt. Cough was hard and profuse, with rusty expectoration. He had severe pain in his left axillary region, under seventh and eighth ribs. On physical examination, I found consolidation of the left lower lobe, with numerous subcrepitant râles over this area.

Treatment.—I gave him at once 60 grains of bisulphate of quinin and ordered 15 minims of tincture of iron every 3 hours.

October 13. Temperature was 101; pulse, 100; respiration, 24. He complained of less pain in his side, and the sputum had become clear; respiration was easy, and cough loose. Thirty grains more of quinin were administered; the iron was continued.

October 14: Temperature was 99.5; pulse, 88; respiration, 20. Cough was loose, with profuse mucopurulent expectoration; there was slight pain in the left side. Twenty grains of quinin were administered, and the iron was continued.

October 15: Temperature was 98; pulse, 68; respiration, 16. There was slight pain in the left side. He had severe cough; the expectoration continued about the same. Elixir of iron, quinin and strychnin was continued for 5 days, and then the patient was discharged.

CASE 3.—*History.*—October 21 was called in to see Mrs. A.

I found that eight days previously she had been delivered of a seven-pound girl by a midwife, and on the fifth day of her puerperium she was seized with severe pain in the right side, followed by a severe chill, after which she began to expectorate rusty sputum.

Examination.—Her temperature was 103.6; pulse, 120, and respiration, 40. She was practically unable to cough on account of the severe pain in right side. On physical examination, I found consolidation of the right lower lobe; no evidence of vaginal or uterine inflammation, except what one would expect after a normal delivery.

Treatment.—Fifty grains of sulphate of quinin were given, followed in one hour by 25 more. One-half grain of codein was ordered every three hours to relieve pain.

October 25: Temperature was 100; pulse, 92; respiration, 26. The pain in the left side was relieved; the sputum was still rusty. She had not taken the last 25 grains of quinin on account, as she said, of the bitter taste. Thirty grains of quinin were administered and the iron continued in 15-minim doses every 3 hours.

October 26: Temperature was 98.6; pulse, 76; respiration, 18. There was no pain in side, except on coughing.

October 27: Temperature was normal; pulse, 100, and respiration, 20. There was still severe cough. A cough mixture was ordered every 3 hours.

October 28: Temperature, pulse and respiration were normal. Cough mixture ordered continued for 3 days, at which time she was discharged, well.

Remarks.—In conclusion, I wish to state that the only other remedy that I find comparable to the action of quinin and iron in pneumonia is the antiphlogistic serum in diphtheria. My recommendation is to begin the use of quinin and iron as early as possible. The only difficulty I experience in the administration of quinin and iron in pneumonia is the fact that I am obliged to give the medicine myself.

DR. E. M. CARPENTER'S CASE REPORTS.

CASE 1.—*Patient.*—A. V., aged 21, Mexican, laborer, was first taken sick Aug. 8, 1905; first seen August 10, and was admitted to hospital August 11, 10:45 a. m., with a temperature of 102.6; pulse, 120, and respiration, 38. Examination showed pneumonia, involving the lower lobe of the right lung. Quinin, 30 grains, was administered at 11:30 a. m. and 15 grains more one hour later. At 7 p. m. temperature was 102; pulse, 116; respiration, 32.

August 12: At 7 a. m. temperature was 101.2; pulse, 112; respiration, 40. Patient slept well during the night. At 12:45 p. m. temperature was 104.4; pulse, 120; respiration, 40. Thirty grains of quinin were administered and 20 grains more one hour later. Tincture of iron, 15 minims, was ordered given every 3 hours. At 7 p. m. temperature was 101.6; pulse, 112; respiration, 36.

August 13: At 6 a. m. temperature was 101; pulse, 92; respiration, 30. At 12 p. m. temperature was 102; pulse, 83; respiration, 24. Ten grains of quinin were ordered every hour for 3 hours. At 7:45 p. m. temperature was 103; pulse, 96; respiration, 32. Thirty grains of quinin were administered and 15 minims of tincture of iron were ordered given during the night.

August 14: At 6 a. m. temperature was 101.4; pulse, 100; respiration, 32. At 1 p. m. 40 grains of quinin were administered and iron continued. At 4 p. m. temperature was 100.4; pulse, 88; respiration, 24.

August 15: At 6 a. m. temperature was 98.2; pulse, 68; respiration, 24. The iron was continued.

August 16: Temperature, pulse and respiration were normal.

August 17: Patient was discharged from the hospital, well.

CASE 2.—*Patient.*—J. A., aged 19, Mexican, occupation, carman in mines.

Examination.—Patient was first seen Feb. 17, 1905, at 9 p. m. He was in the midst of a severe chill, which lasted nearly an hour; his temperature was 104.6; pulse, 140; respiration very rapid. Examination showed lobar pneumonia, involving the right lower lobe.

Treatment.—Sixty grains of quinin were administered at 9:20 p. m., followed by 30 grains more one hour later.

February 18: At 8 a. m. temperature was 101; pulse, 100; his general condition was much brighter. He was transferred to the Ronquillo Hospital, arriving there at 11 a. m. The hospital record shows the following chart:

February 18: At 11 a. m. temperature was 100.8; pulse, 96; respiration, 32. Fifteen grains of quinin were administered and 15 minims of tincture of iron ordered every 3 hours. At 7 p. m. temperature was 99.8; pulse, 83; respiration, 28.

February 19: At 6:30 a. m. temperature was 99.8; pulse, 80; respiration, 19. At 4 p. m. temperature was 98; pulse, 53; respiration, 16.

February 20 and 21: His temperature, pulse and respiration remained normal, and so continued until the morning of February 22, when he was given his clothes and permitted to walk about the hospital. Watching an opportune time while the ward tender was temporarily absent from the ward, he deserted the hospital, making his exit through the back door, and disappeared. On February 28, at 11 a. m., he was returned to the hospital with a temperature of 104; pulse, 130; respiration, 48, and in a very pronounced septic condition. He rapidly grew worse and expired the night of March 2.

OBSERVATIONS OF THE QUININ AND IRON TREATMENT IN PNEUMONIA.

First.—Large doses of quinin given during the initial chill or stage of congestion may materially modify the course of the disease and in some cases abort it.

Second.—Large doses given when the disease has progressed well into the second stage, or stage of red hepatization without treatment, has a decided influence on the temperature and pulse, reducing the former, as well as the latter, which is steadied and increased in volume. These cases all terminate by lysis instead of crisis.

Third.—Large doses of quinin and iron given in the later stage of pneumonia, when no previous treatment has been given, have a beneficial action in controlling the temperature and pulse. In those neglected cases where sepsis is manifested to its fullest extent, an unfavorable result must naturally be expected.

CONCLUSIONS.

The first attention rendered on admittance to the hospital is a warm bath, followed by a calomel or phosphate of soda purge. The initial dose of quinin is administered in from one to three hours later, provided the stomach is not disturbed. If the temperature has reached 105 or over, from 60 to 70 grains of quinin sulphate are given, as the initial dose, followed in one hour by usually one-half of the first dose. If the temperature ranges between 103 and 104, from 40 to 50 grains are given, as above. If a lower temperature is found, 40 grains may be given. This is the smallest dose I would advise as the initial one.

I begin the administration of tincture of iron within three or four hours after the second dose of quinin is administered in doses ranging from 10 to 15 minims every two to six hours, depending on the condition of the pulse. In the event of the temperature rising to 101 or 102, after it has reached the normal or subnormal mark, I administer from 40 to 50 grains of quinin at one dose, and continue the iron in 15 minim doses every three or four hours.

I strongly advise against any compromise in the way of dividing the doses of either quinin or iron during the active pneumonic stage. Occasionally the stomach will become rebellious, but as a rule this may be overcome by chlorotone or pepsin and guaiacal. I dress my patients with as light-weight clothing as possible, provide thorough ventilation and encourage them to take plenty of liquid nourishment.³

3. So many physicians have expressed a desire to visit Cananea and witness my work that I extend a cordial invitation to all who are interested in it to do so at their convenience.

THE FORMATION OF THE CORPUS LUTEUM IN THE GUINEA-PIG.*

LEO LOEB, M.D.
PHILADELPHIA.

HISTORY OF RESEARCH.

Three considerations make it desirable to undertake a detailed study of the development of the corpus luteum of the guinea-pig.

1. Although a number of very careful investigations on the development of the corpus luteum have been published within the last ten years, there are a number of essential points about which different writers still disagree. It is not necessary to give a review of the literature on this subject, as this has been done repeatedly within recent years.¹ In regard to the development of the corpus luteum of the guinea-pig, there exists a short paper of Bellov,² who does not give distinct statements in regard to the age of the different corpora lutea which he describes. His results are in some important points opposed to the results obtained in other animals by different investigators. The most recent paper on the development of the corpus luteum which refers, in part at least, to the guinea-pig is by Jankowski,³ who states that the corpus luteum is formed by theca interna and that the granulosa disintegrates after the rupture of the follicle. His conclusions are based on insufficient evidence, as he has not examined a consecutive series of ovaries.

2. Former investigations into the normal and pathologic anatomy of the ovaries⁴ made it desirable to determine the origin of the cells which are characteristic of the corpus luteum. Similar cells can be found in certain pathologic new formations of the mammalian ovary. For an understanding of the processes leading to those new formations a study of the development of the normal corpus luteum was desired.

3. The formation of the corpus luteum represents a very interesting instance of growth, which constitutes an apparent transition between the processes found in wound healing and between processes observed in tumor growth. The structures recently described by me in the ovary of the guinea-pig show a still closer resemblance to "transitory tumors." The study of the development of the corpus luteum in the guinea-pig is, therefore, of a general pathologic interest.

MICROSCOPIC EXAMINATION OF OVARIES.

Sixty ovaries of thirty, mostly (about three months old), guinea-pigs, were used and cut into serial sections. Zenker's fluid, paraffin and celloidin, hematoxylin and eosin were used. At certain stages, which were of greater importance, more ovaries were investigated than at others.

Copulation was observed and the ovaries were used at

the following periods after copulation: Six hours, $7\frac{1}{4}$ hours, 9 hours (two guinea-pigs), 10 hours, 11 hours, $11\frac{1}{2}$ hours, 12 hours (two guinea-pigs), $12\frac{1}{4}$ hours, $12\frac{1}{2}$ hours, $13\frac{1}{4}$ hours, 15 hours, 17 hours 50 minutes, 22 hours, 24 hours, 25 hours 50 minutes, 28 hours, 30 hours 50 minutes, 32 hours 20 minutes, 34 hours, 36 hours, 38 hours, $49\frac{1}{2}$ hours, $50\frac{1}{2}$ hours, 60 hours, $74\frac{1}{2}$ hours, $77\frac{1}{2}$ hours, $100\frac{1}{2}$ hours, 127 hours.

1. At Six Hours After Copulation (Celloidin).—No ruptured follicle is visible.

2. At Seven and One-Quarter Hours After Copulation (Celloidin).—Place of rupture is visible. Granulosa is preserved. In some of the granulosa cells karyorrhexis is present. Most of the cells are well preserved. Only very little extravasated blood is found in the ruptured follicle. Theca interna and granulosa can easily be distinguished. Theca interna is hyperemic. The granulosa cells are long drawn out. This guinea-pig was born a short time before copulation.

3. At Nine Hours After Copulation (Celloidin).—Two corpora lutea are present in one ovary. The place of rupture is visible. The lumen of the cavity persists. In one of the corpora lutea a part of the granulosa penetrates through the place of rupture into the abdominal cavity and lies on the germinal epithelium. Liquor folliculi is still present and it is drawn out in fibers. The granulosa is well preserved, only near the place of rupture the covering of the granulosa is very imperfect. Mitoses can not be seen in the granulosa cells. Some of the granulosa cells which have been lying free in the central cavity are karyorrhectic. Mitoses are present in the theca interna, which is hyperemic. At most places the demarcation between granulosa and theca interna is not sharp. At some places, however, the granulosa is somewhat detached from the theca interna and both layers can be easily distinguished. No blood is present in the ruptured follicle, with the exception of the immediate neighborhood of the place of rupture. Theca interna and granulosa form several folds. The granulosa cells are drawn out in the direction of the place of rupture. The theca interna cells are likewise drawn out at some places. Polynuclear leucocytes are present in the theca interna.

4. At Nine Hours After Copulation (Paraffin).—Ovaries are hyperemic; no ruptured follicle is present. Three old corpora lutea are visible.

5. At Ten Hours After Copulation (Paraffin).—A small cavity is preserved in each of the ruptured follicles. Liquor folliculi is present in the cavity. Polynuclear leucocytes are found in the central cavity. The granulosa is well preserved. The cells are partly vacuolar. Some of the central granulosa cells are karyorrhectic. The large majority of the granulosa cells are very much dilated. They contain polynuclear leucocytes. At some places between the vessels large cells are found which present the same appearances as granulosa cells. No mitoses can be seen in the granulosa cells. Mitoses are present at the borderline between theca interna and granulosa; they are probably situated in the interna cells. Granulosa and theca interna form folds.

6. At Eleven Hours After Copulation (Paraffin).—The place of rupture of the follicle is open. The corpus luteum is not prominent over the surface of the ovary. A small central cavity is present. In a few sections a few red blood corpuscles can be seen in the central cavity. The granulosa is well preserved. Many granulosa cells, especially the centrally situated cells, show karyorrhexis. Some of the cells are vacuolar. Mitoses are not visible in the granulosa. The theca interna forms protrusions into the granulosa at some places. The blood vessels of the theca interna are very much dilated. Some of the granulosa cells are horizontally arranged (parallel to the theca interna); in some places, however, this arrangement does not exist. The interna cells may assume a polygonal shape with a round or oval nucleus. Such cells which are found around the blood vessels can not be distinguished from granulosa cells. Mitoses can be found in the theca interna cells. The line of demarcation between granulosa and theca interna is not sharp. (Two ruptured follicles.)

7. At Eleven and One-Half Hours After Copulation (Par-

allin).—Two ruptured follicles. Place of rupture is still open; a small cavity is present. The opening at the place of rupture is very narrow. The follicle is very little prominent over the surface of the ovary at the place of rupture. The granulosa is well preserved. The granulosa cells are partly vacuolar. Cells of the inner half of the granulosa are drawn out into long threads. The nuclei in these cell threads become partially dissolved. A mitosis can be seen in the granulosa near the place of rupture. The direction of the spindle corresponds to the traction which is exerted toward the place of rupture. At one place two parallel rows of fusiform cells are seen extending into the granulosa from the theca interna. Mitoses are present in the theca interna near the border of the granulosa. The line of demarcation between theca interna and granulosa is not sharp, and some of the mitoses may therefore possibly belong to granulosa cells. Mitoses are present in the theca interna near the blood vessels and also at the border between theca interna and externa. Mitoses seen in the interna belong in part to dividing endothelial cells of capillaries. The theca interna cells may be very large, and those cells can not be distinguished from granulosa cells.

8. *At Twelve Hours After Copulation (Celloidin).*—Place of rupture is still visible; the cavity of the ruptured follicles preserved. Liquor folliculi is drawn out into fibers and some granulosa cells are drawn out in the same direction; the granulosa is well preserved. Hemorrhages are present in the tissue near the place of rupture. No mitoses are visible; the theca interna is very hyperemic.

9. *At Twelve and One-Quarter Hours After Copulation (Paraffin).*—Three ruptured follicles are present. The place of rupture is still open. The central cavity is preserved. Liquor folliculi (or a viscid fluid of a similar character) is present. In one follicle this fluid protrudes through the place of rupture. The red viscid mass in the cavity is at least in part produced through the disintegration of the inner granulosa cells, the nuclei of which may become dissolved. The granulosa cells of the inner layer can be drawn out into long fibers in which the nuclei may disappear. In the whole, the granulosa is well preserved, although it is in part vacuolar. Karyorrhetic cells are visible in the central part of the granulosa. A number of mitoses can be seen in the granulosa cells, in the outer, middle and inner layers of the granulosa. The diasters are arranged according to the direction in which the cells are drawn out. In the monaster stage the chromatin is sometimes drawn out in the same direction. In most places a sharp line of demarcation exists between the granulosa and the theca interna. Especially when the blood vessels and cells of the theca interna are running radially toward the granulosa it is difficult to determine where the granulosa begins. The distinction is easier when they are arranged in a horizontal direction. At places the line of demarcation between the two layers is still visible. Mitoses are present at the border between the two layers, and it is sometimes impossible to decide with certainty whether the mitoses belong to granulosa or to theca interna cells. The blood vessels are especially dilated near the place of rupture. Many mitoses are present in the interna. Some belong to endothelial cells of capillaries; others are found in cells near the blood vessels. Sometimes the central part of such a cell is in contact with the capillary, although the peripheral parts of the cell are removed from the vessel wall. It is frequently impossible to decide with certainty whether or not we have to deal in such cases with endothelial cells. The cells of the theca interna can be large and indistinguishable from the granulosa cells. Mitoses can also be present in endothelial cells of the blood vessels of the theca interna.

10. *At Twelve and One-Half Hours After Copulation (Paraffin).*—Place of rupture is still visible, but the follicle is no longer open. The granulosa cells of the opposite sides are in close contact; in this way the mouth of the follicle is closed. The defect in the granulosa at the place of rupture is repaired by the close attachment of the granulosa cells at the place of rupture. The ruptured follicle forms a little prominence over the surface of ovary at the place of rupture. A small cavity is present in the closed follicle. The granulosa cells are in part vacuolar. The nuclei of some of the inner gran-

ulosa cells become karyorrhetic, and some cells become dissolved. In many places the theca interna and granulosa are not distinct; the theca interna cells are large. At other places the line of demarcation is clear. The endothelial cells of the capillaries of the theca interna may become large and round. Mitoses are present in theca interna cells. Mitoses are also present in theca externa cells and in endothelial cells of the blood vessels of the theca externa. Blood vessels have not yet entered the granulosa.

11. *At Fourteen and Three-Quarter Hours After Copulation (Paraffin).*—Two ruptured follicles are present. The follicles are closed merely through the granulosa. A small cavity with a little granular matter is seen in the center of the follicles. Many polynuclear leucocytes are present in the central cavity. A number of cells become dissolved in the central cavity. Near the place of rupture dilated blood vessels and lymph vessels are visible. Extravasated blood is also present in the connective tissue near the place of rupture. The granulosa is well preserved; its cells are partially drawn out; no blood vessels and connective tissue can be seen in the granulosa. The line of demarcation is visible between granulosa and theca interna at some places, not at others. Theca interna cells are in part large and polygonal. The blood vessels of the theca interna begin to assume a radial arrangement. At such places the cells of the theca interna and granulosa present frequently the same appearance, and the theca interna and granulosa can therefore not be distinguished. At other places the blood vessels of the theca interna are arranged horizontally, and here theca interna and granulosa can be distinguished. Mitoses are present in different parts of the theca interna near the blood vessels. When they are situated at the borderline between theca interna and granulosa, it is difficult to say to what kind of cells these mitoses belong. A number of the endothelial cells of the capillaries of the theca interna are much swollen, and it is sometimes difficult to determine whether or not a mitosis seen in the immediate neighborhood of a capillary belongs to such an endothelial cell. Many blood vessels of the theca interna are much dilated. The leucocytes seen in the interna stain frequently strongly red with eosin; the polynuclear leucocytes nearer the central cavity take less eosin.

12. *At Fifteen and One-Quarter Hours After Copulation (Celloidin).*—The follicles are closed by granulosa. Connective tissue has not yet regenerated at the place of rupture. A small cavity is present in the center of the follicles. The central mass which stains red with eosin is in part produced by disintegrating granulosa cells. Very little or no blood is present in the central cavity; a few leucocytes are, however, visible in the central cavity. Small hemorrhages may be found in the connective tissue near the place of rupture. The granulosa is well preserved. A few cells are disintegrated in the center. No vessels are visible in the granulosa. The borderline between the granulosa and the theca interna is wavy. Where the interna forms a fold its blood vessels are dilated; they are also dilated near the place of rupture. Mitoses are present in the theca interna, and at the borderline between the theca interna and granulosa. At some places a sharp line of demarcation exists between the theca interna and granulosa; at others no sharp line is visible. The theca interna is partly also drawn out and its blood vessels are dilated.

13. *At Seventeen Hours and Fifty Minutes After Copulation (Celloidin).*—The ruptured follicles are closed by granulosa and by a homogeneous mass which stains red with eosin. Polynuclear leucocytes are present in this mass. The cavity of the follicle is small and does not contain blood. The follicle is somewhat prominent over the surface of the ovary. The lymph vessels in the alboginea near the place of rupture are dilated. In the inner zone of the granulosa there is a little karyorrhexis present. A part of the central granulosa cells are long drawn out and produce fibers when they disintegrate. No blood vessels or connective tissue can be seen in the granulosa. A part of the granulosa protrudes into the cavity. On the whole, the granulosa is well preserved, and mitoses can be seen in different parts of the granulosa. The boundary line between the granulosa and theca interna is wavy. The demarcation between these two layers is not sharp, neither is the theca interna sharply separated from the theca externa. Mitoses

are present in the interna, in the endothelial cells of blood vessels as well as near the blood vessels. Two ruptured follicles are seen.

14. *At Twenty Hours After Copulation (Paraffin).—*A small cavity lies in the ruptured follicle. The place of rupture is closed by a red staining homogeneous mass. Near the place of rupture extravasation of blood is seen in the connective tissue and the lymph vessels are dilated. Old corpora lutea are present in both ovaries. The size of the granulosa cells is about the same as fifteen hours after copulation. The granulosa presents a vacuolar appearance. No blood vessels or connective tissue are visible in the granulosa. At many places no sharp line of demarcation exists between the theca interna and granulosa. At others a layer which is very poor in nuclei separates both layers. The cells of the theca interna frequently can not be distinguished from the granulosa cells, and at some places the interna seems to have disappeared. Mitoses are present in cells of the theca interna and in endothelial cells of its blood vessels. At some places the latter take a radial direction toward the granulosa. At the border between theca interna and granulosa mitoses can be seen. In this region some cells show karyorrhexis. Near the place of rupture mitoses are also visible in the theca interna. Mitoses are likewise present at the border between theca interna and externa. Mitoses are, furthermore, found in endothelial cells of blood vessels of the theca externa near the place of rupture, at a place where many large capillaries are seen, which are in part perhaps newly formed.

15. *At Twenty-two Hours After Copulation (Paraffin).—*Two ruptured follicles are closed by cells which are large and resemble the granulosa and large theca interna cells. Capillaries are seen in this tissue. Spindle-shaped cells cover the large cells. The spindle cells may be either connective tissue cells or regenerating cells of the germinal epithelium. Mitoses are seen in spindle cells as well as in the large cells and in the capillaries and in the connective tissue of the albuginea near the place of rupture. In the connective tissue near the place of rupture red blood corpuscles are still present. The central cavity of the new follicle begins to enlarge; it is larger in the one follicle than in the other. Both corpora lutea are protruding over the surface of the ovary. No boundary line is visible between granulosa and theca interna; the cells of both layers show the same character. The number of cell layers and the size of the cells of the corpus luteum are not markedly different from those of former stages. The central granulosa cells are still vacuolar. From the neighborhood of the blood vessels of the former interna tubes are formed by two parallel layers of drawn-out, spindle-shaped cells, and extend into the former granulosa about half way from the central cavity or still further. The direction of these tubes is radial. In the endothelial cells of the former theca interna, which are often very large, mitoses are present; mitoses are likewise seen in cells lying directly in contact with the endothelial cells. In the theca interna and externa many leucocytes are seen, which stain strongly with eosin. The blood vessels of the theca interna and of the surrounding connective tissue are much dilated. Some old corpora lutea are present in these ovaries.

16. *At Twenty-four Hours After Copulation (Celloidin).—*A small prominence of the follicle is visible at the place of rupture. The follicle is closed by the granulosa; the granulosa at the place of rupture is covered by cells, which may be either connective tissue cells or cells of the germinal epithelium. The germinal epithelium, however, has certainly not yet completely regenerated. Only little blood extravasation is present at the place of rupture. The central cavity of the follicle is closed. The theca interna and granulosa can not very well be distinguished. Mitoses are present at the border between the two layers, and it is difficult to recognize to which of these two layers the mitoses belong. Blood vessels are only found in the outer zone of the follicle; they are not very dilated. No connective tissue or blood vessels are visible in the former granulosa.

17. *At Twenty-five Hours After Copulation (Paraffin).—*The cavity of the corpus luteum is much larger. Pressure is exerted on the cells which line the cavity; they are flat. The

number of cell rows or the size of the cells is not markedly changed. No line of demarcation between the granulosa and theca interna can be seen. The blood vessels of the theca interna are much dilated. Mitoses are present in the endothelial cells of the capillaries. Mitoses are also present in the long-drawn out cells which invade the granulosa. The tubes formed by these cells are occluded presumably by the pressure which is exerted by the fluid present in the central cavity. No blood is to be found in these tubes. The pressure exerted from the central cavity is probably also the cause that these rows of new-formed cells do not run in an absolutely radial direction, but in a more oblique way.

18. *At Twenty-eight and One-Half Hours After Copulation (Celloidin).—*Ruptured follicles are prominent over the surface of the ovary at the former place of rupture. The place of rupture is covered by large cells (former granulosa and interna cells) with blood vessels. Spindle cells are also present, which perhaps are regenerating cells of the germinal epithelium. Near the place of rupture mitoses are seen in the albuginea and also in the endothelial cells of the blood vessels. The central cavity is not large and contains a red-staining, granular substance. No line of demarcation between granulosa and theca interna is visible. In the direct neighborhood of the theca interna of the developing corpus luteum, blood vessels are dilated and mitoses are present in the endothelial cells. The capillaries in the peripheral part of the corpus luteum (in the former theca interna) send out processes toward the central cavity. These capillaries do not yet penetrate deeply into the corpus luteum. Mitoses are present in the endothelial cells of these capillaries and also in many cells in the direct neighborhood of the capillaries. It is sometimes difficult to decide whether or not such mitoses belong to endothelial cells. Mitoses are also present in the former granulosa, in cells which have the appearance of granulosa cells, which may nevertheless be immigrated cells. Besides distinct capillaries, we see spindle-shaped cells penetrating into the granulosa. These spindle-shaped cells may in part at least also represent advancing endothelial cells of capillaries. At some places the tubes formed by the ingrowing spindle-shaped cells (endothelial cells) may extend much further into the corpus luteum. The central part of the corpus luteum, near the central cavity, is free from such cells. The direction of the ingrowing cells is a radial one. In the outer part of the developing corpus luteum many polymuclear leucocytes which stain deeply with eosin are seen. Some karyorrhexis and karyolysis are visible in the cells lying in the central cavity. Three developing corpora lutea.

19. *At Thirty-one Hours After Copulation (Paraffin).—*The corpora lutea are closed; the place of rupture is covered by large cells of the character of granulosa and the large theca interna cells and by regenerating cells, which are probably derived from the germinal epithelium. In one of the developing corpora lutea the follicle forms a marked prominence over the surface of the ovary, the prominence consisting mainly in connective tissue rich in blood vessels. The central cavity has increased in size, cells which have the appearance of detached granulosa cells, which show karyolysis and become dissolved are visible in the central cavity; occasionally a string of cells becomes necrotic. A marked tension seems to exist in the central cavity. The cells lining this cavity are stretched very markedly. No distinction exists between granulosa and theca interna. Dilated blood vessels are visible at the border between theca externa and the developing corpus luteum. In the outer part of the latter, capillaries are seen. Mitoses are present in the endothelial cells of these vessels, as well as in the vessels at the border of the theca externa. Mitoses are also seen in cells in the close neighborhood of the capillaries. From these capillaries or from their neighborhood tubes are growing deeper into the former granulosa. In two of the developing corpora lutea these tubes remain open until they almost reach the central cavity; in the third they are not open so far. Mitoses are also seen in the cells of these tubes. The latter do not run entirely radially, but obliquely, and they frequently turn in a horizontal direction at the inner end. At one place a cell tube, which is without doubt a blood vessel, penetrates almost to the central cavity. In that corpus luteum

in which the cell tubes remain open, the course of the latter is more radial than in the other corpus luteum. One old corpus luteum is present.

20. *At Thirty-two and One-Half Hours After Copulation (Paraffin).—*The cavities found in this corpus luteum are very similar to those seen in the corpus luteum of the preceding stage. The developing corpus luteum is closed mainly through the granulosa cells, which occlude the former place of rupture. They are covered by cells, which are probably derived from the germinal epithelium. The similarity between the large granulosa cells and the regenerated cells of the germinal epithelium, which probably cover the wound, is, however, so great that it is impossible to distinguish with certainty between these two kinds of cells. Some of the covering cells degenerate. The connective tissue near the place of rupture is very rich in enlarged blood vessels, whose endothelial cells are frequently seen to be in mitotic division. Some extravasated blood can also be found here. The corpus luteum is not prominent in this ovary; in this case a retraction of the ovary is found at the former place of rupture. The central cavity is large and it contains a little blood; some cells are disintegrating in the central cavity. Granulosa and theca interna can not be distinguished. Mitoses are found in cells of theca externa and in endothelial cells of the capillaries. At places the blood vessels of the theca externa are very much dilated and the surrounding tissue is edematous. The cells which surround the central cavity are arranged in a concentric manner. The central granulosa cells are vacuolar and small; it appears as if the exudate present in the central cavity, by means of the pressure exerted by it, separated these cells. Cell tubes are extending from the periphery of the developing corpus luteum into the central part. In part they almost reach the central cavity. Others turn around at different heights. Some of these tubes are wide open; most of them are closed and seem to be compressed. In one developing corpus luteum they run in a radial direction, in the other their direction is more oblique. Mitoses are present in the endothelial cells of the blood vessels and in the cell tubes, which in all probability represent new-formed capillaries, although some of them may be ingrowing connective tissue. The cells of these tubes which are in mitotic division are sometimes found in the lumen of the tube; in other places at the outer side, and it is not always possible to exclude with certainty that a neighboring cell is in mitotic division. In the developing corpus luteum other mitoses are visible without any apparent connection with the capillaries. The capillaries in the outer part of the corpus luteum are much dilated, and they run in horizontal direction. An old corpus luteum is present.

21. *At Thirty-four Hours After Copulation (Paraffin).—*The place of rupture is covered by germinal epithelium, which, however, does not yet provide a perfect covering. The follicle forms a small prominence at the former place of rupture. The blood vessels near by are dilated. At one place the blood vessels of the theca externa are dilated and the tissue around these vessels is edematous. The capillaries in the neighborhood of the developing corpus luteum are dilated. In the capillaries of the young corpus luteum mitoses are present, even near the central cavity. At various points cell tubes, which are probably newly formed capillaries, give off branches; the cell tubes may split in several branches. The cells lining the central cavity are flat, perhaps as a result of the pressure exerted by the fluid in the central cavity.

22. *At Thirty-six Hours After Copulation (Celloidin).—*The central cavity is much enlarged. The fluid filling it seems to exert a strong pressure on the corpus luteum. The corpus luteum represents a vesicle with a relatively thin wall traversed in a radial direction by cell tubes and spindle-shaped cells, which latter, perhaps, are connective tissue cells. Mitoses are frequent, especially in the outer part of the corpus luteum; they are, however, also present in the inner half near the central cavity. They can be found in endothelial cells and in the spindle-shaped cells of the corpus luteum. They are also present in the direct neighborhood of the endothelial cells. A part of the capillaries run in a horizontal direction. The cells surrounding the central cavity are flat. They are probably granulosa cells, although it can not be excluded with

certainty that they are immigrated connective tissue cells. No line of demarcation exists between granulosa and theca interna.

23. *At Thirty-eight and One-Half Hours After Copulation (Paraffin).—*The corpora lutea protrude somewhat over the surface of the ovaries at the place of the former rupture. Long drawn-out cells, which are probably regenerating cells of the germinal epithelium, cover this prominence. The central cavity of the corpus luteum is very large. The shape of one corpus luteum is markedly irregular; protrusions of the corpus luteum into the surrounding tissue are formed. No demarcation exists between theca interna and granulosa. In the outer half open capillaries are present; they run radially or horizontally. In the inner half open tubes are also present, but frequently no lumen can be seen between the rows of spindle cells, which grow into the inner half and which may split in different directions. At one place large capillaries traverse almost the whole thickness of the corpus luteum. Mitoses are present in the endothelial cells of the capillaries and in cells lying in contact with the capillaries. The majority of the mitoses are found in the outer half. There are, however, mitoses present near the inner cavity. The cells of the outer half of the corpus luteum are different from the more centrally situated cells, insofar as the latter are more vacuolar than the former. Two old corpora lutea are present.

24. *At Forty-nine and One-Half Hours After Copulation (Celloidin).—*The corpora lutea are closed; they form small prominences over the surface of the ovary. The wound at the place of rupture has healed. It is covered by cells of the germinal epithelium, which have not yet regained their normal shape, but are still long drawn out. Beneath the germinal epithelium connective tissue of the albuginea is found. The central cavity is larger than at the former stage; new liquor folliculi is present. Spindle-shaped cells line the peripheral part of the central cavity. It is not certain that all of these cells are connective tissue cells; some may be granulosa cells drawn out by the pressure exerted by the liquor folliculi. Some of these cells become transformed into fibers. Leucocytes are present in the central cavity. Parallel rows of spindle-shaped cells, the majority of which are probably new-formed endothelial cells of capillaries, traverse the corpus luteum; they may penetrate to the central cavity or they may form loops enveloping groups of lutein cells. The direction of these capillaries is not entirely radial; they run in part in a horizontal direction, which is perhaps due to the pressure exerted by the liquor folliculi. Many mitoses are found in the endothelial cells and in cells in their immediate neighborhood. A part of the invading spindle-shaped cells may be connective tissue cells.

25. *At Fifty and One-Half Hours After Copulation (Paraffin).—*The corpora lutea are closed and covered by germinal epithelium. The latter cells are still spindle-shaped. Beneath the germinal epithelium the connective tissue of the albuginea covers the former place of rupture. One corpus luteum protrudes only slightly over the surface of the ovary, the other somewhat more. The central cavity is still present, although somewhat encroached on by connective tissue which envelops the central part of the cavity in concentric layers. The blood vessels pass through the whole corpus luteum so that at such a place very little or no lutein tissue is left. The outlines and shape of the corpus luteum may become very irregular, probably as a result of this ingrowth the corpus luteum of blood vessels forms irregular protuberances into the surrounding connective tissue. Probably because of the better blood supply the character of the corpus luteum cells changes; they are less vacuolar and stain well with eosin. The capillaries are still partially compressed; they run either radially or bend over into a horizontal direction; they may also split into two branches at different levels, even near the central connective tissue. They penetrate into the central connective tissue. Probably as a result of this new formation of capillaries a small hemorrhage with many leucocytes is found in the central cavity. A new formation of capillaries has apparently likewise taken place in the theca externa at a place where the latter protrudes into the corpus

luteum. Many mitoses can be seen in the endothelial cells of the capillaries in all parts of the corpus luteum, near the border of the theca externa as well as near the central cavity. Mitoses are also present in cells which are in direct contact with the capillaries. An endothelial cell in mitotic division may, with its fusiform ends, overlap neighboring endothelial cells. Mitoses are likewise seen in the cells of the connective tissue which fills the peripheral part of the central cavity. The large majority of all mitoses are certainly in endothelial cells. It sometimes appears as if the connective tissue cells of the central connective tissue might be derived from the endothelial cells of the capillaries. It is, however, not possible to prove it. Both corpora lutea have about the same character. Some old corpora lutea are present.

26. *At Sixty Hours After Copulation (Celloidin).*—Two corpora lutea of the same character are present. The periphery of the central cavity is filled by connective tissue and new-formed capillaries which penetrate into the connective tissue from the corpus luteum tissue proper. The latter is traversed by capillaries, mostly in a radial direction. The cells of the corpus luteum are somewhat larger than at earlier stages and stain well. The new-formed blood vessels have probably a favorable effect on the character of the lutein cells. Many mitoses are present in endothelial cells of the capillaries in different parts of the corpus luteum, and also in other cells which are probably lutein cells. Mitoses are also present in the connective tissue cells of the central cavity. Hemorrhages are seen in the central cavity and in the connective tissue of the central cavity probably as a result of the intrusion of new capillaries in the central cavity.

27. *At Seventy-four and One-Half Hours After Copulation (Paraffin).*—The corpora lutea are not much larger than in the former stage. The central cavity is not yet entirely filled out by connective tissue, which latter is arranged concentrically in the peripheral part of the central cavity. The corpus luteum cells are well formed. The cell membrane is distinct. Some vacuoles appear in cells, which are large and assume the character of typical lutein cells. Mitoses are present in endothelial cells of the capillaries and in cells near capillaries which are probably lutein cells. Mitoses are also visible in the central connective tissue. Many polynuclear leucocytes are found in the corpus luteum.

28. *At Seventy-seven and One-Half Hours After Copulation (Celloidin).*—The central cavity is almost entirely filled by connective tissue. Mitoses are seen in capillaries of the central connective tissue. The corpus luteum cells are larger than in former stages and are well formed. The corpus luteum as a whole is also larger. No distinction exists between granulosa and theca interna. Many capillaries traverse the corpus luteum. Mitoses are present in the endothelial cells of the blood vessels and also in cells near the capillaries. Such cells are probably lutein cells. Mitoses in lutein cells are found in the central as well as in the peripheral parts of the corpus luteum. Such mitoses may cause a protrusion of the endothelial cells of the capillaries.

29. *At One Hundred and One Half Hours After Copulation (Celloidin).*—The central cavity is filled by connective tissue. In this connective tissue capillaries are present. The corpus luteum proper is relatively large, the central connective tissue at the place of the former central cavity occupies only a relatively small area. The corpus luteum cells are large and show well-formed vesicular nuclei. The cytoplasm is somewhat spongy; it stains purple with hematoxylin and eosin. Mitoses are present in endothelial cells of capillaries, as well as in lutein cells. One corpus luteum still protrudes somewhat over the surface of the ovary. The connective tissue covering the former place of rupture is compressed so that the typical alboginea has not yet been restored. Polynuclear leucocytes are present in the peripheral part of the corpus luteum. The character of a typical corpus luteum has been acquired.

30. *At One Hundred and Twenty-seven Hours After Copulation (Celloidin).*—The corpus luteum is typical. Large capillaries traverse the corpus luteum. The central connective tissue is small in quantity. The lutein cells stain well (purple). No mitoses can be seen. The corpus luteum forms many irregular protrusions into the surrounding tissue.

DISCUSSION OF RESULTS.

1. Ovaries of thirty guinea-pigs were examined. The ovaries of two animals showed no ruptured follicle. In one of these cases, six hours after copulation, the time elapsed after copulation had perhaps been too short for the rupture to take place. In the other the ovaries were examined nine hours after copulation and some hyperemia was found, but there was no indication that a follicle was near rupturing.

2. One of the questions most discussed is: Is the granulosa preserved after the rupture of the follicle, and does it take part in the formation of the corpus luteum? It can be stated with certainty that the granulosa remains preserved and takes part in the formation of the corpus luteum. A distinct defect in the granulosa can be noticed at the place of rupture nine and eleven and one-half hours after copulation. The cells are on the whole well preserved; in part they show some vacuoles. From twelve and one-half hours on, the defect in the granulosa is no longer visible, as the granulosa cells which surround the place of rupture form one continuous layer. The vacuolar character is especially noticeable in the centrally-situated cells. From fifty to sixty hours on, the lutein cells become somewhat larger and stain well. On the fourth day the cells show the typical appearance of the lutein cells. On the fifth day we see typical lutein cells with well-formed vesicular nuclei. The cytoplasm is spongy and it stains purple with hematoxylin and eosin. The change in the character of the cells seems to coincide with the penetration of the blood vessels into the former granulosa. When the whole corpus luteum is supplied with a network of capillaries the cells seem to get larger and to stain better.

3. Nine hours after copulation, a short time after the rupture has taken place, a part of the granulosa on the surface of the ovary is seen extending through the place of rupture into the peritoneal cavity. This is a frequent occurrence and tumors are not known to originate from such displaced cells. After twelve and one-quarter hours liquor folliculi penetrates through the place of rupture into the peritoneal cavity instead of granulosa; the place of rupture is now closed and internal pressure causes the granulosa to protrude partially into the cavity of the follicle. That can be seen seven-teen hours fifty minutes after copulation.

4. Not all the granulosa cells remain alive. In the first hours after the rupture, and as late as eighteen hours after copulation, a number of centrally-situated granulosa cells show karyorrhexis and disappearance of their nuclei, followed by dissolution of the cells. At twenty hours we see some karyorrhexis at the border between the granulosa and theca interna, and as late as twenty-eight and one-half hours and thirty-one hours karyorrhexis and karyolysis and dissolution of some cells take place.

5. At an early period after the rupture some granulosa cells are long drawn out in the direction of the place of rupture. It appears as if traction were exerted on the cells in that direction. A number of such cells may degenerate, lose their nuclei and form fibers which stain red by eosin. A part of the red-staining mass which is present in the central cavity is therefore a direct product of degenerating cells.

6. In a similar way the viscid red-staining mass which fills the cavity of the follicle can be drawn out into fibers nine and twelve hours after copulation. At an early period after the rupture a red-staining, homogeneous mass or a somewhat granular material is still

present in the central cavity. From forty-nine and one-half hours on the liquor follicle is increasing again.

7. As stated, a number of granulosa cells are lost after the rupture of the follicle. To compensate for this loss mitotic divisions take place in granulosa cells. One mitosis is visible near the place of rupture eleven and one-half hours after copulation. At twelve and one-half hours we see a number of mitoses, diasters and monasters, in all layers of granulosa. The diasters are drawn out as the cells are drawn out—toward the place of rupture. At seventeen hours fifty minutes we see mitoses in different parts of the granulosa. In other specimens mitoses can be seen at the margin of granulosa and theca interna, and it is difficult to be sure whether some mitoses lie in the outer part of the granulosa or in the inner part of the theca interna. At twenty-six hours and at later stages we see mitoses in the cells which invade the granulosa from the theca interna. At twenty-eight and one-half hours we see in the area of the former granulosa mitoses in cells which may have been granulosa cells, but which possibly were immigrated cells. No mitoses could be seen in the granulosa nine, ten, eleven and twelve hours after copulation.

8. Soon after the rupture of the follicle, nine and ten hours after copulation, the boundary line between granulosa and theca interna form folds. At eleven hours the theca interna forms protrusions into the granulosa at some places. At eleven and one-half hours two parallel rows of fusiform cells are seen at one place to extend into the granulosa from the theca interna; at fifteen and one-half hours and seventeen hours fifty minutes the border between granulosa and theca interna is wavy. The theca interna cells may be drawn out in the same direction as the granulosa cells.

9. Soon after the rupture of the follicle the theca interna is very hyperemic. This condition is marked until fifteen hours after copulation. From twelve hours up to thirty hours the blood and lymph vessels near the place of rupture are dilated. The hyperemia extends to the connective tissue surrounding the place of rupture, especially to the albuginea. From twenty-two hours on, the blood vessels of the theca externa become dilated and the hyperemia passes to the connective tissue directly surrounding the corpus luteum. The hyperemia is quite marked thirty-one and thirty-four hours after copulation. This change in the area of hyperemia from theca interna to theca externa is perhaps due to the pressure exerted in the corpus luteum itself after the rupture has been closed more firmly.

10. Mitoses in the theca interna can be seen soon after the rupture up to the time when the theca interna and the granulosa can no longer be distinguished in the corpus luteum. From nine to twenty-four and thirty-one hours mitoses can be seen near the granulosa as well as in the peripheral part of the theca interna, in endothelial cells and in interna cells proper at the side of the capillaries. It is not possible in each case to decide with certainty whether a mitosis belongs to an endothelial cell or to a cell lying in close proximity to an endothelial cell. Mitoses in endothelial cells are present as early as eleven and one-half hours after copulation and can be seen at different periods up to thirty-two and one-half hours; at that time one can only approximately determine which part of the vessels belongs to the former theca interna and which belongs to the former granulosa. Between twenty and thirty hours mitoses are present near the place of rupture in endothelial cells as well as in other cells.

11. In the theca externa mitoses can also be seen in endothelial cells of blood vessels as well as in connective tissue cells. They are present twelve and one-quarter and twelve and one-half hours after copulation. The larger number of mitoses is visible in the theca externa, and in the blood vessels of the theca externa between twenty and thirty-two and one-half hours, perhaps in connection with the hyperemia which is more marked here at that period. At a later period, fifty and one-half hours after copulation, capillaries seem to be newly formed in the theca externa, and these capillaries enter the corpus luteum.

12. A number of cells of the theca interna become large and polygonal and can no longer be distinguished from the granulosa cells. At some places such cells can be seen between the blood vessels ten, eleven and twelve and one-half hours after copulation. The endothelial cells of capillaries may likewise swell. The interna cells assume more and more this character, and if the blood vessels of the interna run in a radial direction toward the granulosa, both layers are in part or in their entirety indistinguishable. At seven and one-quarter hours both layers can still be easily distinguished. From nine hours to twenty hours in many cases the line of demarcation can be made out. At fourteen and three-quarter hours they can, for instance, easily be distinguished where the theca interna cells and their blood vessels show a concentric arrangement to the follicle. At twenty hours a zone, which is very poor in nuclei, separates both layers. Where the direction of the capillaries is a radial one the distinction between the two layers is no longer possible. Both layers take part in the formation of the corpus luteum.

13. Mitoses in blood vessels of the theca interna can be seen very early after the rupture of the follicle. Twenty hours after copulation the blood vessels of the theca interna have a radial direction in some places. Twenty-two hours after copulation, tubes, formed by two parallel layers of spindle-shaped cells and with a radial direction, extend from the neighborhood of the blood vessels of the former interna half way or further into the former granulosa. At twenty-four hours we see blood vessels only in the outer zone of the follicle. At twenty-six hours cell tubes enter the former granulosa. At twenty-eight and one-half hours we see capillaries in the peripheral part of the corpus luteum (the former theca interna) sending out processes toward the central cavity. Cell tubes extend at some places far into the corpus luteum, the central part near the central cavity remaining free from capillaries. The direction is radial. At the same time we see spindle-shaped cells which represent endothelial cells of capillaries or perhaps connective tissue cells entering the former granulosa. At thirty-one hours capillaries are present in the outer part of the corpus luteum. From these outer capillaries or from their neighborhood cell tubes are growing deeply into the former granulosa. In two of the corpora lutea these tubes preserve a distinct lumen until they almost reach the central cavity and their course is radial; in the third corpus luteum they do not remain open so far and their course is more oblique. At the central end the cell tubes turn frequently in a horizontal direction. Between thirty and forty hours such cell tubes traverse the corpus luteum either radially or obliquely. They have a lumen in the outer part of the corpus luteum. In the inner half open tubes are also present, but frequently no lumen can be seen between the rows of spindle cells. The rows of spindle cells give off branches which run obliquely or horizontally and begin to en-

velop the corpus luteum cells. Besides the distinct cell tubes we see spindle-shaped cells without apparent connection with such cell tubes. As early as thirty-eight and one-half hours after copulation at one place large capillaries traverse almost the whole thickness of the corpus luteum. At forty-nine and one-half and at fifty and one-half hours capillaries pass through the corpus luteum to the central cavity. In the connective tissue which is present in the peripheral part of the central cavity the tubes may lose their lumen. These capillaries may split into two branches at different levels, even near the central connective tissue. At some places the blood vessels and connective tissue pass directly from the theca externa through the whole corpus luteum in a radial direction into the central tissue. At such a place very little corpus luteum tissue is left. At sixty hours and later many well developed capillaries pass through the corpus luteum.

Two questions arise: Are the spindle-shaped cells invading the granulosa, endothelial cells of capillaries, or are they in part ordinary connective tissue cells; and what is the origin of these cells? We see that these cell tubes originate near the capillaries of the former theca interna. The endothelial cells of the latter show at the same time mitoses. These facts make it probable that at least a great part, perhaps all, of these tubes are derived from the blood vessels of the theca interna. The fact that a lumen is not present in all cell rows might be explained by the pressure exerted at certain stages of the developing corpus luteum from the direction of the central cavity toward the periphery. Nevertheless it is likely that a part of the spindle-shaped cells are connective tissue cells, but I could not find any definite indication that the ordinary theca interna or theca externa cells infiltrate the granulosa. This fact, however, does not exclude the possibility that nevertheless such an infiltration might take place. At a later stage we see blood vessels and connective tissue pass from the theca externa to the central part of the corpus luteum.

14. Between thirty and forty hours mitoses are found in the newly-formed cell tubes of the corpus luteum. They are present in the central, and more frequently, in the peripheral part of the corpus luteum. Mitoses are also found in spindle-shaped cells which do not distinctly belong to the cell tubes, and in cells which lie in close approximation to the cell tubes. Not in every case is it possible to state with certainty whether a mitosis is seen in a cell belonging to the tubes described above or to a lutein cell lying near it, because during mitotic division the endothelial cells may change somewhat their position; they may protrude toward the lumen of the cell tubes as well as toward the outer side.

From fifty to sixty hours in all parts of the corpus luteum many mitoses can be seen in endothelial cells and in cells which are situated between the capillaries. These latter cells are probably lutein cells. Mitoses are also present in the connective tissue of the central cavity. The same conditions prevail up to 100 hours after copulation. At 127 hours mitoses are no longer visible.

15. The place of rupture of the follicle is open in the first few hours. It becomes occluded by granulosa cells twelve and one-half hours after copulation. Six hours later we find between the occluding granulosa cells a homogeneous mass which stains red with eosin. Perhaps some liquor folliculi was pressed out through the granulosa, or it is possible that it was formed through the degeneration of some granulosa cells. Between twenty-two and thirty hours we find the place of rupture occluded by larger corpus luteum cells which contain capillaries.

These large cells again are covered by spindle-shaped cells which may be in part at least regenerating cells of the germinal epithelium; there were perhaps connective tissue cells admixed. Mitoses can be found in the endothelial cells of the blood vessels as well as in the large cells.

Mitoses are also present in the connective tissue of the albuginea near by. Between thirty and forty hours no marked change takes place; the regeneration of the germinal epithelium becomes more marked, mitoses still occur and the surrounding connective tissue is hyperemic. The covering of the albuginea is, however, not yet perfect. About fifty hours after copulation the regenerating cells of the germinal epithelium are in part still somewhat spindle-shaped; beneath them the connective tissue is visible.

We have to assume that the first temporary occlusion by granulosa cells is caused by the pressure of the ovarian tissue surrounding the follicle, only somewhat later an actual wound healing takes place and leads to a solid closure of the opening.

16. That a pressure of the surrounding ovarian tissue is exerted on the ruptured follicle is perhaps also indicated by the fact that after eleven and one-half hours we find a more or less marked prominence of the ruptured follicle over the surface of the ovary. It is quite marked twenty-two hours and thirty-one hours after copulation. It is, however, not necessarily always present. We find even a retraction at the place of rupture thirty-two and one-half hours after copulation.

17. After the rupture of the follicle a small cavity remains preserved in the center of the follicle. As soon as the granulosa covering of the follicle becomes stronger and with the simultaneous ingrowth of capillaries the cavity begins to enlarge, slowly from twenty-two to thirty hours after copulation, more rapidly between thirty and forty hours. At forty-nine and one-half hours the cavity is large, new liquor folliculi is formed, and connective tissue becomes visible in the peripheral parts of the central cavity. At seventy-seven and one-half hours the cavity is almost entirely filled by connective tissue. At 100½ hours the central cavity is entirely filled by connective tissue which contains capillaries.

18. The increase in the size of the central cavity, combined with the increase in the quantity of the liquor folliculi, seems to exert a pressure on the structures surrounding the central cavity. This is indicated, for instance, by the flattening of the centrally situated granulosa cells, which is noticeable twenty-six hours after copulation. From now on flattened cells line the central cavity. At first they are in all probability granulosa cells. The flattened cells are probably granulosa cells between thirty and forty hours, although at that period connective tissue cells may be admixed. After fifty hours we have to deal mainly or exclusively with connective tissue cells. As indications of pressure exerted by the fluid of the central cavity may perhaps be considered the fact that at early periods the cell tubes traverse the corpus luteum, frequently not in a directly radial, but in a more oblique direction, and that from twenty-six hours on the blood seems to be pressed out of the vessels of the corpus luteum proper into the surrounding connective tissue for a certain period. This interpretation, however, is only a tentative one.

19. It is an interesting fact that the connective tissue which fills gradually the central cavity grows along the border of the cavity in a concentric direction and that in this way it gradually fills the central cavity. Mitoses can be seen in the connective tissue cells of the central

cavity at different periods, for instance, fifty and one-half and seventy-four and one-half hours after copulation. Cell tubes and distinct capillaries grow into it. At fifty and one-half hours cell tubes can be seen, and at sixty hours distinct capillaries are visible. Mitoses are also found in endothelial cells of capillaries. It is uncertain whether the mode of ingrowth of connective tissue is due to contact irritability of the connective tissue or to the pressure exerted by the fluid of the cavity.

20. At various periods the developing corpora lutea show a very irregular shape and they form protrusions into the surrounding connective tissue. Corpora lutea of that character were visible at thirty-eight and one-half hours, at fifty and one-half hours and 100½ hours. In one case (at fifty and one-half hours) it appeared as if the ingrowth of large blood vessels from the theca externa had caused those irregular formations.

21. The rupture of the follicle seems to be accompanied by very little hemorrhage. In a number of follicles we see a slight amount of extravasated blood in the connective tissue near the place of rupture as late as thirty-two hours after copulation. In some follicles we see a small number of red blood corpuscles in the central cavity eleven, twelve and fifteen and one-quarter hours after copulation. Later, at fifty and one-half hours and at sixty hours we see slight hemorrhages in the central cavity. This blood has, however, probably a different origin and is in all likelihood extravasated from the new-formed blood vessels of the corpus luteum.

22. Polynuclear leucocytes are seen in the central cavity, and in the theca interna soon after the rupture of the follicle, in variable numbers. The leucocytes in the central cavity take up the eosin to a much less degree than the leucocytes which have just left the vessels. Later, at forty-nine and one-half hours and fifty and one-half hours, we see leucocytes in the central cavity. Their presence is in part due to hemorrhage from the new-formed vessels.

23. The size of the corpus luteum and of the individual cells does not increase much at early stages of the developing corpus luteum. At seventy-seven and one-half hours, however, the corpus luteum begins to become distinctly larger and at 100½ hours the central connective tissue occupies a relatively small area as compared to the lutein tissue proper.

24. We found that the large theca interna cells and the granulosa cells assume the same appearance in the ruptured follicle of the guinea-pig. We are, therefore, unable to distinguish between the two kinds of cells composing the corpus luteum after development has advanced to a certain stage. We can state that the large cells which are characteristic of the corpus luteum are derived from two different sources, namely, from the granulosa and from the theca interna. Although these two varieties of cells can not be distinguished morphologically after the corpus luteum has been formed, we can not say with certainty that there might not exist some chemical or physicochemical differences. We have, however, no indications of the presence of such differences, which become especially doubtful as we know that both the large cells of the theca interna as well as the granulosa cells may contain lutein, and that both may show the same tendency to fatty changes.

25. If we now compare the formation of the corpus luteum with the atresia of the follicles we see two principal differences between the development of these two structures. (a) During the atresia of follicles the granulosa degenerates entirely; in the corpus luteum it remains preserved and the cells increase in size and in

number. A number of granulosa cells degenerate, however, even in the follicle which has ruptured. (b) In the atretic follicle the ingrowth of connective tissue predominates. A new formation of blood vessels does not take place, or is only very slight. In the corpus luteum, on the other hand, the new formation of blood vessels and their ingrowth into the former granulosa, and even into the central connective tissue, is very prominent.

For a further deeper analysis of these differences of growth, experimental investigations will be necessary.

A PHYSICO-CHEMICAL THEORY OF FERTILIZATION.*

MARTIN F. FISCHER, M.D.

AND

WOLFGANG OSTWALD, Ph.D.

SAN FRANCISCO.

INTRODUCTION.

Within the last few years our conceptions of the physical state of protoplasm have undergone a series of changes in consequence of which a number of long-debated physiologic problems have been settled. No one advance has contributed nor promised to contribute more toward the understanding of certain cell phenomena, both from their morphologic and physiologic aspects, than the recognition of the colloidal nature of protoplasm.

It is our purpose in the following pages to show, if possible, that the fertilization of the ovum by the spermatozoon represents another cell process which finds its explanation in the colloidal nature of the egg protoplasm, and it is to the arguments which point in this direction that we wish to call attention. As it is impossible in the limited time allowed to meet all the various criticisms which might be raised against our theory of fertilization, we would refer the interested listener to our earlier and more extensive paper on this subject where the effort to meet these objections has been made.¹

As any adequate theory of fertilization must be applicable not only to the normal process of fertilization of the ovum by a spermatozoon, but also to parthenogenesis both natural and artificial, it may not be amiss to give here a table of the various kinds of fertilization with which we are thus far acquainted.

I. Normal Fertilization. (Egg and spermatozoon both present.)

1. Normal egg and normal spermatozoon.
2. Normal egg and incomplete spermatozoon.
3. Egg without nucleus and normal spermatozoon.
4. Polyspermia.

II. Parthenogenesis. (Egg without the spermatozoon).

1. So-called natural parthenogenesis, combined with such external conditions as increase in temperature, freezing, desiccation, etc.
2. Artificial parthenogenesis.
 - A. Through withdrawal of water: osmotic fertilization through electrolytes and non-electrolytes.
 - B. Through specific chemical methods:
 - (a) Through salts.
 - (b) Through acids (organic and inorganic).
 - (c) Through alkalis.
 - (d) Through other chemicals (alcohol, ether, chloroform, alkaloids, perhaps colloidal substances, etc.).
 - C. Through changes in temperature.
 - D. Through mechanical means (shaking, brushing, squirting, etc.).

DEFINITION OF THE TERM FERTILIZATION.

As the conception of fertilization is as various as the number of authors who have written on the subject, it becomes necessary for us first of all to define this term. In doing so we have to distinguish between a physiologic and a morphologic definition. The majority of definitions are of the latter kind. If we try to give a physiologic definition of the function of spermatoozon, we can say that it causes the egg to develop. With the other functions of the spermatoozon, such as its power to transmit the characteristics of the male, we have nothing to do. Physiologically, fertilization may, therefore, be defined as the impulse to development.

It is more difficult to give a morphologic definition of fertilization. Normally, this process consists in the entrance of a spermatoozon into the egg. The entire spermatoozon is, however, not necessary, for as soon as this cell has entered the ovum, the function of the tail-piece is at an end. Only the head and middle are of importance in causing the development of the egg. Of these two the head-piece grows steadily larger, becomes vesicular, and, as the male pronucleus, ultimately coalesces with the female pronucleus. Experiment has shown, however, that the head of the spermatoozon is by no means necessary in order to bring about the development of the egg, for by the proper methods it can be kept quiescent inside the ovum, and development nevertheless takes place. The power of bringing about the development of the ovum resides under normal circumstances in the middle piece of the spermatoozon. If we follow the history of this part we find that shortly after the entrance of the spermatoozon into the ovum the middle piece becomes surrounded by a light area which grows steadily in size and becomes very conspicuous, in that the granules of the egg protoplasm arrange themselves radially about it. We recognize in this description the formation of the astrosphere, and as will become apparent later, with the formation of the astrosphere the specific processes of fertilization are at an end.²

It is self-evident that parthenogenetic development, both natural and artificial, must differ morphologically in many respects from normal fertilization. In one particular, however, all, both normally and artificially, parthenogenetic eggs show the same histologic structure as normally fertilized eggs, namely, in the formation of the astrospheres. It has been shown by Zeilson that in eggs which have been caused to develop parthenogenetically by artificial means every point of histologic similarity to normally fertilized eggs may be lacking save one, the formation of astrospheres. But in the very constancy of this structure we find another argument to show that the formation of the astrosphere is the most essential morphologic part of fertilization, and that it is it which gives the impulse of development to the egg.

We believe that we can show that all those methods which can be used to bring about the formation of an astrosphere in an egg or its development are such as can be employed to bring about the conversion of a liquid colloid or sol of the approximate constitution of egg protoplasm into a solid colloid or gel, and that conversely almost every method which physical chemistry has at its disposal to bring about the conversion of a sol into a gel, is or may be used to bring about the normal or artificial development of the ovum. Simple comparison of the table of fertilization methods given

above with the list of methods given below, which may be employed to convert a sol into a gel, already points in this direction. It must not be thought, of course, that the gelation in the ovum occurs exactly the same way as the gelation of a sol in a test tube. Certain external conditions influence the process within the egg, which modify it somewhat. These external conditions which make the formation of the astrosphere a specialized gelation will be discussed further on. It will be seen in this discussion that the ordinary laws of colloids suffice entirely, to our minds, to explain even this specialized gelation. As the final and perhaps strongest argument for the correctness of our ideas we shall use the experimental results of Bütschli, Alfred Fischer and Rumbler, whose work on the formation of artificial astrospheres in certain colloids, such as albumose, gelatin, agar-agar, etc., has well merited the astonishment and praise of the scientific world.

PHYSICAL CHEMISTRY OF COLLOIDS.

According to most investigators, colloids differ from crystalloids, in that the former do not, on solution in water, form entirely homogeneous, that is to say, true solutions, but inhomogeneous ones. The colloid remains suspended in the solvent, or to put it more correctly, the colloidal solution represents a mixture of two substances, which are only partially miscible in each other. Between the typical colloids, on the one hand, which have practically no osmotic pressure, and do not alter the boiling or freezing point of the solvent in which they are suspended, and the typical crystalloids on the other, which possess all these properties to a most marked degree there are, of course, a large number of intermediate bodies, which lean more or less strongly toward one or the other of these divisions.

A colloid has the power of existing in two states, a so-called soluble or sol state, and an insoluble or gel state. When the colloid is in the latter condition it is often said to be coagulated, precipitated or gelatinized. Certain differences, no doubt, exist between these terms, and the physical states of aggregation which they represent, but as physical chemists still use the terms indiscriminately and synonymously, we shall do so, too.

The change from the sol state to the gel is determined by a number of external conditions. These are tabulated in brief below.

1. *Effects of Temperature.*—A colloidal solution is capable of existing in the sol state only within certain limits of temperature. When these limits are exceeded the colloid passes from the sol into the gel state. In regard to their behavior toward changes in temperature we distinguish between two classes of colloids. There are those first of all which pass from the sol to the gel state when the temperature is increased to a certain point. To this class belongs, for example, egg albumin, which coagulates on heating. A second class of colloids made up of those which pass into the gel state through a decrease in temperature. To this class belong the ordinary gelatins, which become solid on cooling below a certain temperature. As an increase in the temperature will cause the gel in the latter case to return to the sol state, this class of colloids is spoken of as heat-reversible colloids in contrast to the former group in which a decrease in the temperature will not re-establish the liquid state of the colloids. Egg albumin is, therefore, a heat irreversible gel. In regard to the behavior of colloids toward other external conditions also, the process of gelation is said to be reversible or

² Boyer's Das Problem d. Befruchtung, Jena, 1902, p. 8.

irreversible. It is of interest to note in passing that a heat reversible colloid which has once passed into a gel can not be reconverted into a sol by only a slight increase in temperature above the point at which gelation occurred. Ordinarily, gelatin, for example, which gels at 0 C., does not become liquid again on heating until 26 C. is reached. Within the limits of temperature, which are of biologic importance, a heat reversible colloid, therefore, behaves as an irreversible one, a fact of importance in our further considerations.³

2. *Effects of Concentration.*—A colloid can exist as a sol only within certain limits of concentration. It has been shown by Gutbier and Resenschek that a colloidal solution of gold is precipitated if the water is allowed to evaporate from it in a vacuum or under the influence of heat. It must not be forgotten, however, that the evaporation of the water is associated with an increase in the concentration of the electrolytes, which may be present as impurities in the colloidal gold. As the next paragraph will show these can by themselves bring about a precipitation of a sol if sufficiently concentrated, so that if not entirely responsible these electrolytes might at least aid in the precipitation of the colloid, the concentration of which was being raised by evaporation of the water holding the colloid in suspension. That the increase in the concentration of the colloid by itself plays an important rôle in its coagulation is shown, however, by the fact that a sol can be precipitated the more easily through some external agency the more concentrated it is.

3. *Effects of Salts.*—Sols can be converted into gels through the addition of salts. It has been shown by Hardy that the coagulating power of a salt is determined by the valency and the sign of the charge of its ions. The coagulating ion always has an electrical charge opposite to that of colloidal particle. In this way positively charged ions coagulate only negatively charged colloidal particles. The coagulating power of an ion increases with its valency, not in a simple proportion, but according to the following formula, in which R represents the valency and K the coagulating power:

$$R^1:R^2:R^3=K^1:K^2:K^3$$

What exceedingly small traces of salts suffice to bring about the coagulation of certain colloids may be imagined when we cite the fact that at 16 C. colloidal ferric hydroxid is precipitated by potassium sulphate when 1-gram molecule of the salt is present in 4,000 liters of water.⁴

4. *Effects of Acids and Alkalies.*—Acids, both organic and inorganic, and alkalies can also cause the coagulation of a sol, but as in the case of salts, their effect is dependent on the electrical change of the colloidal particles. Electro-positive particles are precipitated by alkalies and electro-negative ones by acids. Generally speaking, no amount of an acid will precipitate an electro-positive colloid, and no amount of an alkali will coagulate an electro-negative one.

5. *Effects of Non-Electrolytes.*—A large number of non-electrolytes are known which cause the coagulation of sols. We will mention here only ether, alcohol and chloroform which interest us particularly. The coagulating power of these substances is familiar to everyone from their daily use in physiologic chemistry for the precipitation of proteins, etc.

6. *Effects of Colloids on Colloids.*—One colloid may be used to coagulate another. In order that this may

occur, however, it is necessary that the two have opposite electrical charges. If they are charged with the same kind of electricity they do not affect each other.

7. *Effects of Mechanical Agitation.*—One of the commonest means of bringing about the coagulation of a sol, and one which is in nearly all cases connected with the means given above for causing a sol to pass into the gel state, is mechanical agitation. It is a generally known fact that colloids to which, for example, a salt has been added, often require hours or days before coagulation sets in, but pass at once into the gel state if they are slightly shaken. In considering the effects of mechanical agitation it is to be remembered that it is the more effective the nearer the colloid is to the critical point; that is to say, the point at which the sol passes into the gel.

HISTOLOGIC STRUCTURES OF COLLOIDAL SOLUTIONS.

Having outlined the external conditions which determine the change from the sol state to the gel, we must discuss briefly the structures of colloidal solutions in these two states. Certain investigators believe that sols are optically homogeneous solutions. More microscopic examination is, however, sufficient to show that many sols are inhomogeneous, and, as has been shown by recent investigations, aided by the ultra-microscopic methods of Sidentopf and Zsigmondy, even those sols which were formerly considered homogeneous are, according to the more generally accepted opinion, really inhomogeneous. Sols represent suspensions of exceedingly finely divided insoluble particles. The size of individual particles varies not only in colloidal solutions of different substances, but even in sols of the same substance.

Gels differ markedly in structure from sols. It has been shown by the work of Fleming, Bütschli, Alfred Fischer and Hardy that most, if not all, coagulated colloids have either an open net, a honeycomb or a fibrillar structure in the spaces of which the liquid portion of the colloid is found. The fibrils or the meshes of the net or honeycomb are made up of the colloid containing but little solvent, while the interstices are filled with a liquid composed of the solvent and a little colloid. It is not without importance that the liquid filling the interstices is not composed of pure water, but contains some, even though it be only a small amount, of colloidal material.

The change from the sol state to the gel is characterized by a change in the special arrangement of the suspended particles. While in a sol the colloidal particles are distributed evenly through the solvent, they are clumped and arranged in rows when gelation occurs. This rearrangement of the suspended particles gives rise to the gel structure. Because of this approximation during gelation of the suspended particles, the latter are no longer able to hold as much solvent as before and fluid is given off. This separation of liquid usually evidences itself in an external separation of the solvent from the gel. A familiar illustration is found in the expression of the serum from coagulated blood, which represents the formation of a gel. At other times special means, such as slight pressure, are required to make the separation an apparent one.

Whether an open net or a honeycomb structure is formed is dependent on a number of circumstances. Most colloids give rise to an open-net structure, where they coagulate. Those colloids which are present in protoplasm and which coagulate to form a honeycomb structure (for example, gelatin) will produce an open-

3. Hardy: Jour. of Physiology, 1899, xxiv, p. 119.

4. Hardy: Loc. cit., p. 398.

net structure when not too highly concentrated. It seems probable, therefore, that in protoplasm these colloids also give rise to an open-net structure.

We have yet to discuss the origin of the fibrillar structure. This represents only a modification of the other two, and comes to pass when a certain external factor, a mechanical one, comes into play. A fibrillar structure is formed when gelation occurs under a directive stress. According to Bütschli, for example, a fibrillar structure can be produced in gelatins, which, under ordinary circumstances, show a honeycomb structure, if the colloid is stroked with a glass rod while cooling.

Also of interest in our further considerations is the time required for the conversion of a sol into a gel. Generally speaking, we can say that this change occurs very rapidly. By this is meant that when the external gel-producing agent, for example, the temperature, has reached the critical point, sol passes into the gel in an exceedingly short time or instantaneously.

THE PHYSICO-CHEMICAL NATURE OF FERTILIZATION.

We wish to show now that the formation of the astrosphere, or what amounts to the same thing, according to our definition, the process of fertilization, represents a gelation occurring under special conditions. In order to do this it must be shown first of all that the protoplasm of the normal unfertilized egg exists in the sol state. That the protoplasm of the egg represents a colloid or a mixture of colloid, we can now regard as settled. That this colloid or mixture of colloids exists in the sol state is rendered probable by the following morphologic and physico-chemical facts. The protoplasm of the unfertilized egg is stated by various observers to be either entirely homogeneous or finely granular. The coarser protoplasmic inclusions, such as oil droplets, etc., are, of course, not of importance in our discussion. The structure of the resting egg is, therefore, the same as that given above for the structure of sols in general. In apparent contradiction to this homogeneous or finely granular structure of protoplasm stands the observation of Bütschli that all protoplasm has a honeycomb structure even in the uncoagulated state. This honeycomb structure of the uncoagulated state must not be confounded with the honeycomb structure which appears in many coagulated colloids. The structure attributed by Bütschli to uncoagulated protoplasm is entirely compatible with physico-chemical observations, for, as has been pointed out by Quincke, such a structure is the logical result of the intimate mixture of two or more colloids of different surface tensions. That several colloids are present in the egg is indicated by the fact that a number of different colloidal substances (different proteins) can be extracted from the egg, and also by the morphologic fact that different portions of the egg protoplasm do not have the same optical activity.

From a physico-chemical standpoint the sol nature of unfertilized egg protoplasm is found in its remarkable fluidity, a property which is markedly diminished when the astrospheres are formed. Dr. Frank Bancroft has called our attention to fertilization experiments in marine material, in which the astrospheres formed after fertilization of the egg could be squeezed out of the egg as solid plugs. This fact is at once an argument for the liquid character of egg protoplasm in general and the more solid character of the astrosphere.

Histologic study of the process of fertilization brings further evidence, which indicates that we have to do with a process of coagulation in the egg. This is shown by the fact that after the entrance of the spermatozoön,

or after the initiation of parthenogenetic development by any means whatsoever, the previously homogeneous or finely granular egg protoplasm becomes more coarsely granular, and little by little the fibrils of the astrosphere are formed. This description corresponds with that given above, of the formation of the open-net and fibrillar structure in a colloidal solution undergoing coagulation. In certain eggs various observers have described the presence of a histologic structure even in the resting egg. In these cases also, however, the granules previously present become larger and the protoplasmic structures more distinct, besides assuming a definite orientation when the astrospheres are formed.

It was pointed out above that the process of coagulation in a colloid is attended by a liberation of water, which frequently evidences itself by an external separation of colloid and solvent. Evidence of such a separation of colloid and water is found in the formation of the fertilization membrane in the eggs of many species which have been made to develop either by natural or artificial means. When the fertilization membrane is formed, the volume of the egg protoplasm proper becomes less and the egg transmits light less easily than before.

The fact that no fertilization membrane is formed in many eggs can not be taken as an argument against the correctness of the idea that the process of fertilization is essentially a process of coagulation for certain eggs, such as those of the sea urchin, which always show a fertilization membrane when fertilized by a spermatozoön, may not do so when made to develop artificially. Yet even these parthenogenetic eggs may be made to show fertilization membranes if only certain salts are present in the sea water.

We have yet to explain a marked difference between the process of coagulation of an ordinary colloid in a test tube and the formation of the astrosphere, namely, the specific orientation of the gelation in the egg. The chief reason for this difference is probably to be sought in the fact that in the egg the coagulation takes place from one point only, while in a test tube it occurs simultaneously from an innumerable number of points. Through this localization of the coagulation in the egg the ordinary process of gelation is markedly modified. The gelation spreads in a wave radially from the coagulating point. Those portions of the protoplasm which lie nearest this point are the first to coagulate. The coagulation is, however, not without design as when an ordinary sol gels, but occurs in definite directions so that the radiating structure of the astrosphere is formed. It was shown above that fibrils are produced whenever the ordinary coagulation of a colloid is modified by being made to occur under a directive stress. We believe that the formation of the fibrils of the astrosphere in the egg can be explained in the same way as the formation of a fibrillar structure in the coagulation of any colloid. The sources of the directive stress in the egg during the formation of the astrosphere can not be discussed in detail here, but changes in surface tension, currents produced through the separation of colloid and solvent, etc., during the coagulation may by themselves or together serve as the source of this directive force.

The collection of coagulated particles first about the coagulating point (the middle piece of the spermatozoön in normal fertilization) gives rise to the clear area found in the center of every astrosphere. The gradual growth of the astrosphere is an expression of the gradual spread of the process of coagulation from the center of the

astrosphere outward. It is interesting to note, finally, that the time required for the production of an astrosphere in an egg and an ordinary coagulation in a sol is about the same.

The facts given above lead us to believe that the formation of the astrosphere, or what amounts to the same thing, according to our definition, the process of fertilization, is identical with a localized and oriented gelation.

In our concluding paragraphs we shall bring as further evidence that the laws governing colloidal solutions actually suffice, according to our minds, to explain the by-no-means simple structure of the astrosphere, the work of Bütschli, Alfred Fischer and Rhumbler. These observers have produced artificially, in unorganized colloids, by the same methods and means which have been employed to produce these structures in eggs, astrospheres, not unlike those found in the ovum. Our theory serves also to harmonize the results obtained by these observers, which, according to them, stand in apparent variance with each other. The recognition of the fact that their experiments are made with colloids and that the means employed to produce the artificial astrospheres are all such as the physical chemist may use to convert sol into gels is the harmonizing element.

In the following table, based on the one formerly given, the attempt is made to point out the coagulating factor in each of the processes of normal or artificial fertilization with which we are thus far acquainted. Perusal of this table will show that all the physico-chemical methods already enumerated for producing gelation in colloids have been successfully used in the production of astrospheres in egg protoplasm, or what amounts to the same thing, for the normal or artificial fertilization of the egg. It indicates at the same time how Bütschli, Alfred Fischer and Rhumbler have succeeded in employing nearly all these methods for the artificial production of astrospheres in unorganized colloids as well.

1. NORMAL FERTILIZATION: EGG AND SPERMATOZOON BOTH PRESENT.

1. *Normal Egg and Normal Spermatozoon.*—The gel-producing factor resides in the spermatozoon. The entire spermatozoon is, however, not necessary, as only the head and middle piece enter the egg, the tail-piece disappearing before an astrosphere is produced. Histologic examination shows that the formation of the astrosphere starts from the middle piece, while the head-piece swells markedly to form the male pronucleus.

2. *Normal Egg and Incomplete Spermatozoon.*—It has been shown by Boveri that the middle piece alone is necessary for the production of an astrosphere. Under certain experimental conditions the head-piece of the spermatozoon can be kept quiescent in the egg, the middle piece alone leading to the formation of an astrosphere.

3. *Egg Without Nucleus and Normal Spermatozoon.*—In this case a normal spermatozoon enters an egg fragment containing no nuclear substance. The formation of an astrosphere occurs in this case also.

4. *Polyspermia.*—Under certain experimental conditions several spermatozoa may enter an egg. Multiple astrospheres corresponding with the number of spermatozoa are produced under these circumstances.

The gel-producing factor in all these cases of normal fertilization is the spermatozoon, or more accurately, the middle piece of this cell. It might be thought that the nucleus, either of the egg or the spermatozoon, plays a necessary rôle in the formation of the astrosphere. That

this is not the case, however, is shown by the experiments of Morgan, who has been able to produce astrospheres artificially by chemical means in egg fragments containing no nuclear matter.

In attempting to point out where in the foregoing table the spermatozoon, or more properly, the middle piece, belongs, we have to remember that the spermatozoon contains at least two or three such factors:

A.—The middle piece is certainly a colloidal substance, or a mixture of such; that is to say, we might have to do in fertilization with the action of one colloid on another. The colloids of the spermatozoon might be enzymatic in character. Familiar examples of coagulating enzymes are pepsin, trypsin and pepsin, which are able to bring about the coagulation of albumoses and peptones. The possible enzymatic character of the spermatozoon has already been pointed out by Loeb.⁵ This conception of the process of fertilization is, however, entirely different from our own in that he believes the fertilizing agent to act as a mere accelerant of a process which occurs in the egg even in the absence of such a fertilizing agent.

B.—The middle piece contains, as does the entire spermatozoon, certain salts, which might act together with the colloidal substances to produce a coagulation. That the presence of these salts in the spermatozoon might play some rôle in the process of fertilization has also been pointed out by Loeb.

C.—Mention must finally be made of the possible mechanical rôle of the movements of the tail piece of the spermatozoon. The mechanical action of the spermatozoon has been especially emphasized by Meltzer,⁶ though he did not, of course, attempt to explain the nature of the change which it produced in the egg.

Which of the gel-producing factors mentioned above plays the chief rôle in the formation of astrospheres can not be determined from the experimental facts which we have at our disposal up to the present time.

We have yet to show that artificial astrospheres can be produced in unorganized colloidal solutions through the addition of another colloid. The best illustrations of this of which we know are certain experiments of Alfred Fischer and Bütschli. The former observer was able to produce artificial astrospheres in gelatin, agar-agar and especially deutero-albumose through the action of dried elder pith nuclei. Bütschli has produced astrospheres artificially in gelatin by sowing into it particles of dried egg albumin. The illustrations are, however, not entirely free from criticism, for the colloids used to produce the astrospheres were not entirely salt free.

II. PARTHENOGENESIS: EGG WITHOUT SPERMATOZOON.

1. SO-CALLED NATURAL PARTHENOGENESIS.

So-called natural parthenogenesis is combined with such external conditions as increase in temperature, freezing desiccation, etc. This method of fertilization is characterized by the fact that the formation of the astrosphere is not brought about through a clearly demonstrable external factor, but that the gel-producing agency resides within the egg protoplasm itself, even though at times the formation of the astrosphere occurs in conjunction with certain external conditions. In parthenogenetic development the polar bodies, which are not thrown off as in ordinary fertilization, seem to be able to assume the gel-producing function of the middle piece of the spermatozoon. We are dealing in this case again with the action of a colloid on a colloid, though

⁵ Loeb, *Am. Jour. Physiology*, 1903, vol. III, p. 470 et seq.

⁶ *Am. Jour. of Physiology*, 1903, vol. IX, p. 251.

the possibility of the co-operation of certain salts present in these polar bodies must not be overlooked. It is interesting to note that in nearly all cases of natural parthenogenesis observed thus far the development of the egg is combined with such external conditions as increase or decrease in temperature, desiccation, mechanical agitation, etc., all of them conditions which may bring about the conversion of a sol into a gel.

2. ARTIFICIAL PARTHENOGENESIS.

A. Through withdrawal of water.

B. Through specific chemical methods.

a. Through Salts.—The most general method of producing artificial parthenogenesis is the osmotic method discovered by Morgan and further developed by Loeb. In attempting to find the gel-producing agent responsible for the astrospheres in this method of fertilization, the one which first comes to mind is the increase in the concentration of the colloids in the egg. The extraction of water from the egg, however, brings about an increase in the concentration of the salts at the same time. Since we are not yet acquainted with an illustration from the realm of physical chemistry of the coagulation of an absolutely pure, that is to say, salt-free colloid, through increase in its concentration alone, we are inclined to believe that in osmotic fertilization we are really dealing with the effects of specific salts.

This view is supported by the biologic fact that artificial parthenogenesis can be produced through specific salts as indicated in the next paragraph, and by the physico-chemical fact that the coagulation of colloids is produced much more readily and generally through salts than by osmotic means. What has been said above holds for osmotic fertilization, whether brought about through electrolytes or non-electrolytes. Of the many substances which have been used for this purpose, we need mention only magnesium chlorid, potassium chlorid, sodium chlorid, etc., solutions of different sugars, glycerin, urea, etc.

We are acquainted also with the formation of astrospheres in unfertilized egg through the action of specific salts. In these water is not given off by the egg, but the entrance of these salts into the egg causes the formation of astrospheres. Under this heading we can mention the parthenogenetic development of chetopterus through the addition of traces of potassium chlorid as first found by Mead and later worked out in detail by Loeb; the parthenogenetic development of amphitrite through the addition of calcium chlorid or calcium nitrate, as found by Martin H. Fischer, as well as the development of stronglyloecentrotus eggs, as found by Herbst, through traces of silver salts.

It is of interest, finally, to make brief mention here of experiments by Morgan, which show that in artificial parthenogenesis, as well as in normal development, the nucleus plays no important rôle in the formation of the astrosphere. Morgan has succeeded in producing astrospheres in egg fragments containing no nuclear matter by treating them with concentrated salt solution of various kinds. As examples of the artificial production of astrospheres we may cite the following: Particles of calcium sulphate in gelatin (Bütschli), diffusion of mercury chlorid or platine chlorid, or the addition of tiny crystals of mercury chlorid, potassium bichromate, etc., to albumose solutions (Alfred Fischer).

b. Through Acids (Organic and Inorganic).—Tichomiroff was the first to produce parthenogenesis arti-

ficially, and this in Bombyx, which he succeeded in making develop through treatment with strong acids. Further experiments in this direction have been made by Loeb and Neilson with star fish eggs, and more recently by Delage. The acids used have been H_2SO_4 , HCl , HNO_3 , H_2CO_3 , etc. Organic acids, when sufficiently concentrated, are equally effective, as has been shown by Loeb. As an example of the artificial production of astrospheres in unorganized colloids through acids, we may cite the work of Alfred Fischer, who was able to produce these structures by allowing osmic or picric acid to diffuse into albumose solutions.

c. Through Alkalies.—J. Loeb has been able to produce cell division in certain marine eggs through the addition of various to the sea water. As a parallel illustration of the production of astrospheres through alkalies we may mention Alfred Fischer, who succeeded in producing these histologic in faulty acid albumins through the addition of alkalies.

It is interesting to note that astrospheres have been produced in eggs of the same species through the addition of either acid or alkalies. Alfred Fischer has found this possible, also in solutions of unorganized colloids. From a physico-chemical standpoint, it seems strange at first sight that acids and alkalies should both be able to produce the same effect in the species of egg. The paradox may, however, be explained by an observation of Hardy, who has found that an alkaline sol of albumin is converted into a gel through the addition of an acid. If more acid is added, however, the gel is redissolved, and an acid sol of albumin is produced. The acid sol of albumin may then again be reconverted into a gel, which can then be changed to an alkaline sol by the addition of an alkali. This indicates how a gel can easily be produced through either the addition of an acid or an alkali.

d. Through Other Chemicals (Alcohol, Etc.).—Mathews has succeeded in causing the parthenogenetic development of sea urchin eggs by treating them transitively with chloroform, ether or alcohol. Mention must also be made under the heading of the work of R. Hertwig, who several years before noted a production of astrospheres in the same species of egg after treatment with strychnin. We are dealing in all these substances with well-known precipitants of colloidal solutions.

e. Through Changes in Temperature.—The parthenogenetic development of star fish eggs has been produced through a lowering of temperature to near the freezing point by Greeley. In discussing the physiologic effects of decrease in temperature, we have to consider two processes. If the temperature is decreased to the freezing point ice is formed, in consequence of which the concentration of the colloids of the egg or the salts dissolved in the protoplasm is increased. Either of these conditions it will be remembered, is effective in determining the formation of gels. If the temperature is not reduced to the freezing point we can look on the coagulation of the colloids of the egg only as a gelatin of a heat-reversible sol (such as gelatin). As Greeley kept the eggs at a low temperature for only a short time, it might be thought that the effects of the lowering of temperature would be reversed as soon as the eggs were returned to room temperature. We learned above, however, from the experiments of Hardy that a heat-reversible gel does not return to the liquid state after gelation when the increase in temperature is only a few degrees.

Mathews and Delage have succeeded in producing cell division in certain marine animals through an increase of temperature. The experiments of Delage are

7 Tichomiroff: Arch. v. Anat. u. Physiologie, 1886, supp. vol. p. 75, and Zoölog., Aug., 1902, p. 25.

not entirely free from criticism. In this case the gel-producing factor is, of course, the increase in temperature.

Through a decrease in temperature Bütschli and Rhumbler have succeeded in producing astrospheres in gelatins, which simulate in a truly striking way those found in developing eggs.

D. Through Mechanical Means.—The first to produce artificial parthenogenesis through mechanical means was Tichomiroff, who succeeded in causing the unfertilized eggs of Bombyx to develop through brushing. Mathews was able to show that the eggs of star fish will develop artificially if shaken or squirted through a pipette. These results have been confirmed and shown to hold true also for the unfertilized eggs of amphitrite and chetopterus by Martin H. Fischer. Through the work of Scott it has been shown that at least two periods exist in the life of the unfertilized amphitrite eggs, during which mechanical agitation is most effective in bringing about their development. The rôle of mechanical agitation in bringing about the precipitation of colloidal solutions has already been discussed above, and needs no further comment here.

Loeb has expressed the view that all unfertilized eggs possess a certain tendency to develop parthenogenetically, that is to say, without being acted on by any external agent. Certain other authors have expressed a belief that it is only necessary to expose the unfertilized eggs of various marine animals, especially star fish, to certain "abnormal" conditions. The latter view is certainly incorrect. We believe that in all cases specific external conditions determine the development of the unfertilized egg. Or to express this in terms of our theory, we can say that the colloidal solutions of the egg protoplasm lie exceedingly near their critical point, that is to say, their coagulation point. To indicate how exceedingly slight these external conditions may be which determine the parthenogenetic development of the egg, we may quote the experiments of Herbst, who found that only after the most careful cleansing "with acids and stiff brush" could he free his dishes which had contained traces of silver salts, from this chemical sufficiently to prevent it from exerting a fertilizing effect. Even the most careful transference of amphitrite eggs from one dish to another is sufficient frequently to cause the development of a certain per cent. of unfertilized amphitrite eggs.

Special Article

THE PHARMACOPEIA AND THE PHYSICIAN.

CATHARTICS.

CHAPTER VII.

The Anhydrid Group.

The active principles in drugs of this group are resinous in character; their chemistry is obscure, but most of them are known to be glucosides. They cause violent irritation and even death in excessive doses and are not commonly used alone unless a strong irritant action is desired. Since they produce very watery stools, they are sometimes used in dropsy, or to sweep away parasites—for instance, after a narcotic tenifuge, such as aspidium.

JALAPA.—U. S.—Jalap, the dried tuberous root of *Ergoninum purga*, gathered in the neighborhood of Jalapa, Mexico, whence its name. The drug was introduced into Europe about 1609; it is now official in all pharmacopœias. The drug should contain not less than 8 per cent. of total resin, but not more than 1.5 per cent. of resin soluble in ether.

Average dose (in powder): 1 gm. (15 grains).

PULVIS JALAPÆ COMPOSITUS.—U. S.—This is a mixture of 35 parts of jalap and 65 parts of potassium bitartrate.

Average dose: 2 gm. (30 grains).

RESINA JALAPÆ.—U. S.—That part of the alcoholic extract which is insoluble in hot water.

Average dose: 0.12 gm. (2 grains).

COLOCYNTHIS.—U. S.—The peeled dried fruit of *Citrullus colocynthis*, a species of cucumber. As "Kolokynthis," this drug was described by Dioscorides and appears to have been well known even before his time; since then it has been in constant use.

Average dose: 0.05 gm. (50 mg. to 1 grain).

EXTRACTUM COLOCYNTHIDIS.—U. S.—

Average dose: 0.030 gm. (30 mg. ½ grain).

EXTRACTUM COLOCYNTHIDIS COMPOSITUM.—U. S.—Compound Extract of Colocynth is a mixture of 16 parts of extract of colocynth, 50 parts of purified loes, 6 parts of cardamon, 14 parts of resin of scammony and 14 parts of soap.

Average dose: 0.50 gm. (7½ grains).

PILULÆ CATHARTICÆ COMPOSITÆ.—U. S.—Compound Cathartic Pills. Each contains:

Comp. ext. of colocynth.....	gr. iss	108
Mild mercurous chlorid.....	gr. i	06
Resin of jalap.....	gr. 1/3	02
Gamboge.....	gr. 1/4	015

Average dose: 2 pills.

PILULÆ CATHARTICÆ VEGETABILIS.—U. S.—Vegetable Cathartic Pills. Each contains:

Comp. ext. of colocynth.....	gr. i	06
Ext. of hyoscyamus.....	gr. ss	03
Resin of jalap.....	gr. 1/3	02
Ext. of leptandra.....		
Resin of podophyllum, an.....	gr. 1/4	015
Oil of peppermint.....	m. 1/8	008

Average dose: 2 pills.

SCAMMONIUM.—U. S.—Scammony, a gum-resin obtained by incising the living roots of *Convolvulus scammonia*, has been known and properly esteemed as an active cathartic for over 20 centuries.

Average dose: 0.250 gm. (4 grains).

RESINA SCAMMONII.—U. S.—Resin of Scammony is that portion of the gum-resin that is soluble in alcohol, but insoluble in water.

Average dose: 0.200 gm. (3 grains).

PODOPHYLLUM.—U. S.—Podophyllum, popularly known as mandrake root or May apple, is said to have been used by the American Indians, but the statement has been repeatedly questioned.

Average dose: 0.500 gm. (7½ grains).

FLUIDEXTRACTUM PODOPHYLLI.—U. S.

Average dose: 0.5 c.c. (8 minims).

RESINA PODOPHYLLI.—U. S.

Average dose (purgative): 0.015 gm. (15 mg. ¼ grain); (laxative): 0.005 gm. (5 mg. 1/10 grain).

LEPTANDRA.—U. S.—Is rarely used in substance.

EXTRACTUM LEPTANDRÆ.—U. S.

Average dose: 0.25 gm. (4 grains).

FLUIDEXTRACTUM LEPTANDRÆ.—U. S.

Average dose: 1 c.c. (15 minims).

ECONYMUS.—U. S.—Econyinus is the dried bark of the root of *Euonymus atropurpureus*.

The Extract (dose 0.12 gm. (2 grains)), and the Fluidextract (dose 0.5 c.c. or 8 minims) are also official.

ELATERIUM.—U. S.—Elatrin, a neutral principle obtained from elaterium, a substance deposited by the juice of the fruit of *Ecballium elaterium*.

Average dose: 0.005 gm. (5 mg. 1/10 grain).

The therapeutics of the anhydrid group may be treated together, as the action of the different members is very similar and there are fewer indications for one, rather than another, in a particular case.

They are all used to some extent in dropsy, but elaterium is the most effective of all in the removal of water. They cause depression, and when this is severe it demands stimulation.

They are rarely used alone; thus scammony, which, in overdoses, has caused death, is used in the compound cathartic

pill; jalap is often combined with calomel or with potassium bitartrate, in the compound jalap powder, which is administered alone. An example of the combination of calomel with jalap is the calomel and jalap powder of the National Formulary, which consists of:

Calomel	3i	32
Jalap	3iii	64

The dose is about 1 gm. (15 grains), or a smaller amount may be given and repeated at intervals of several hours.

Resin of jalap is nearly tasteless and is, therefore, often given to children; it may be mixed with a little sugar for the purpose.

Compound cathartic pills are so well known that they scarcely require further notice. The soap present (in compound extract of colocynth) slowly reduces the mercurous chloride to the black oxid—increasing its effectiveness.

Polophyllum has been called "vegetable calomel" and it was supposed to increase the secretion of bile, but this is not probable. It causes purgation after ten to twelve hours and is very useful in acute constipation.

A suitable form of administration is suggested below, but the possible combinations are endless. The Triplex Pills (N. F.) have the following formula:

R. Purified aloes	gr. ii	13
Mass of mercury	gr. i	1065
Resin of polyphyllum	gr. 1.4	1016

Dr. Jno. W. Francis has used a pill containing about 1 grain, each, of purified aloes, scammony and mass of mercury, with 1.20 minim of croton oil, $\frac{1}{4}$ minim of oil of caraway and enough tincture of aloes and myrrh to make one pill.

Leptandra, eunonymus and some other official vegetable drugs cause purgation, but do not require special mention here.

CAMBODIA.—U. S.—Camboge is a gum-resin obtained from *Garcinia hanburii*.

Average dose: 0.12 gm. (2 grains).

Purgative Oils.

There are but two of these which merit discussion here. Castor oil and croton oil owe their activities to two acids, ricinoleic in the castor oil and crotonoleic in croton oil. The acid does not exist uncombined in castor oil, but is liberated when it reaches the intestine, forming new compounds which are irritant and therefore purgative.

Crotonoleic acid does exist free to a small extent in croton oil, which is, therefore, irritant even when applied to the skin.

Other bland fixed oils are sometimes used as laxatives. Among those which are official are Olive Oil, Cotton Seed Oil, and Expressed Oil of Almond.

OLEUM RICINI.—U. S.—Castor oil, expressed from the seed of *Ricinus communis*, is a pale, yellowish or almost colorless, transparent, viscid liquid, having a faint mild odor, but an offensive taste. It was known to the ancients, but fell into disuse; it was again brought into notice in 1764 by a West Indian physician, who described it as a gentle purgative.

Average dose: 15 c.c. (4 fluidrachms).

Castor oil is very useful in ordinary constipation, and often in diarrhea, where it serves to remove the irritating substance.

Owing to the widespread repugnance to the taste of castor oil, many means have been devised for disguising it. If the mouth is merely rinsed with strong whisky, the oil may be swallowed without discomfort. For children it is given in the form of soda water with syrup of sarsaparilla, or with ginger ale, when it is often swallowed without the child's knowledge.

The following formula is useful for disguising the taste:

R. Spts. menth. pip.	3iiss	10
Oil ricini q. s. ad	3iii	100

Sig.: 15 c.c. (4 fluidrachms) to be taken without further dilution.

Emulsions of castor oil have never been popular, as they but imperfectly disguise its taste. Soft capsules, containing 15 minims each, may be swallowed, and many persons find them unobjectionable. Three or four capsules are given at bedtime.

OLEUM TIGLID.—U. S. Croton Oil. A pale, brownish-yellow fixed oil, expressed from the seeds of *Croton tiglium*; it has a short fatty odor, and a mild, oily, afterward acid and burning taste. (Great caution is necessary in tasting.)

Average dose: 0.05 c.c. (1 minim).

Owing to its irritant character and the violence of its action, croton oil is not generally used as a purgative, but there are conditions in which it is very useful; it may be given in apoplexy, when the patient is unconscious, a drop being placed on the tongue either in the form of an emulsion or on sugar. It is useful when, from any cause, there is difficulty in administering a bulky cathartic, but it is contraindicated in inflammatory conditions of the intestines.

Croton oil is also applied to the skin as an irritant.

Laxative Sweet Substances.

Some of the following substances may be treated under the subject of dietetics, since they are laxative mainly because of the bulk of non-absorbable matter. The dose is large and the action mild—with the exception of Cassia Fistula, which is apt to cause griping.

MANNA.—U. S.—The concrete saccharine exudation of *Fraxinus ornus*. It consists mainly of a peculiar sugar, mannite.

Average dose: 16 gm. (240 grains).

PRUNUM.—U. S.—Prune, the partly dried fruit.

TAMARINDUS.—U. S.—The preserved pulp of the fruit.

Average dose: 15 gms. ($\frac{1}{2}$ ounce).

FICUS.—U. S.—The partially dried fruit.

CASSIA FISTULA.—U. S.—The dried fruit. This and the three preceding articles enter into confection of senna.

Manna is a mild laxative, but it is rarely used alone; it enters into the compound infusion of senna.

Phenolphthalein is not official as a medical substance, but is mentioned in the Pharmacopeia, in the list of reagents and test solutions, as an indicator in acidimetry.

It has attracted some attention of late as a laxative. In combination with soap and salicylic acid, it is being widely advertised under the name of "Probilin."

Since many of the symptoms resulting from indigestion and constipation were formerly attributed to a deficiency in the formation of bile, agents were sought which would increase its secretion. Many of the purgatives now in common use were supposed to possess this property, but the only agent which has been shown by experiment to increase the secretion notably is bile itself.

The precise rôle played by bile beyond the splitting of fats, is still a moot point.

In this connection it may be mentioned that the mineral acids, particularly the dilute nitro-hydrochloric, have been much used for their supposed cholagogue action, this is too slight to give them practical value, but they are useful in many conditions for which a deficiency of bile is supposed to be the cause.

Dr. Philip Shaffer recently gave a woman with biliary fistula about 20 gms. (5 drams) of the purified ox bile in three days, resulting in a notable increase of bile secretion.

The patients' general condition seemed to be but little affected by the absence of bile from the intestine, but fats were not so well borne as in a normal person. This but confirms the experience of other observers, and in this light cholagogues lose much of their importance.

FEL BOVIS.—U. S.—The fresh bile of the ox is only used in the form of:

FEL BOVIS PURIFICATUM.—U. S.—Its use has already been mentioned.

Average dose: 0.5 gm. (8 grains).

(To be continued.)

1. The proprietors of probilin quote Dr. W. Bauermeister of Brunswick, Germany, as authority for the assertion that salicylic acid and sodium oleate are the most powerful cholagogues. This is not in accord with the generally accepted opinion of therapeutists. The same authority states that he had the two drugs put up in pills containing $\frac{1}{2}$ grains of each, adding menthol and phenolphthalein as analeptics and to mildly stimulate intestinal activity. But we are unable to understand why he should add "these pills, named probilin, are difficult to prepare." At least, any competent American pharmacist can readily prepare them. Three or four of these pills taken before retiring are said to be effective.

Clinical Reports

SUCCESSFUL SUTURE OF A PENETRATING WOUND OF THE HEART.

JOHN H. GIBBON, M.D.

Associate Professor of Surgery, Jefferson Medical College; Surgeon to the Pennsylvania and Bryn Mawr Hospitals. PHILADELPHIA.

Within the past three years I have made two contributions to the subject of penetrating wounds of the heart, the last of which was read at a meeting of the College of Physicians in May,¹ 1904, and it is my intention to briefly relate the details of a case of successful suture of a stab wound of the right ventricle and to make a few comments on the symptoms and treatment. This patient is the second one on whom I have reported, the first having died on the operating table.²

Patient.—A. C., aged 38, a well-developed, healthy, colored man, was admitted to the Bryn Mawr Hospital on July 30, 1905, at 12:20 a. m.

History.—He had been stabbed with a "penknife" about one hour previous to his admission. Immediately after the stabbing he was able to walk a short distance, but then fell to the ground and soon became unconscious. His friends brought him to the hospital in a cab.

Examination.—At the time of his admission he was profoundly unconscious, the reflexes were lost, the pupils dilated, skin cold and moist, finger nails cyanosed and respiration very rapid and shallow. There was no pulse in the peripheral vessels and the heart sounds were very distant, rapid and irregular. The patient's clothing was saturated with fresh blood and an examination showed three stab wounds, one at the bend of the left elbow, one just below the edge of the pectoral muscle in the left axilla and a third about three-fourths of an inch to the left of the sternum and on a line with the fourth costal cartilage. This latter wound was more extensive than either of the others and measured about one and three-fourths inches in length, extending upward and outward. At the time of admission the first two wounds were not bleeding, but a small amount of hemorrhage was taking place from the wound over the heart which was partly filled with clot. The area of cardiac dullness was decidedly increased.

Treatment.—The patient was given vigorous stimulation and in about half an hour his condition had improved somewhat and he could be partially aroused. I saw the patient about 1:45 with Dr. Branson, who assisted me in the subsequent operation, and who thought from the symptoms that the man at least had a wound of the pericardium and that this sac was filled with blood, making pressure on the heart.

Operation.—The patient improved considerably after his admission, and when put on the operating table he could be aroused sufficiently to give his name. He had had morphin and atropin, and it took but a small amount of ether to produce anesthesia. An exploration of the wound over the heart showed that the fourth costal cartilage had been completely severed transversely. The wound did not extend beyond the cartilage, and it is this fact which prevented blood escaping readily from the pericardium. When the cartilage was manipulated a quantity of blood escaped between its divided end. The entire cartilage, with a portion of the rib itself, was removed with rongeur forceps. Exploration of the pericardium then showed a wound which would admit the end of the index finger. This wound was increased in size and the pericardium was found filled with blood clot and liquid blood. The patient's pulse had improved under the ether, but it was much fuller and more regular after the evacuation of the pericardium. The sac rapidly filled again with fresh blood, and I had considerable difficulty in locating the wound in the heart itself. In my former case I had no trouble of this kind, as on passing my finger over the surface of the heart it readily discovered the opening. Being unable to discover the wound by digital examination, I put two fingers behind the heart, lifted it up

to the pericardial opening and by rapidly sponging away the blood I was able to see the wound, which was partially filled with clot. It was situated in the right ventricle near the auriculo-ventricular groove. The bleeding from this wound was very free, but could be controlled readily by digital pressure. It easily admitted the tip of the index finger and measured from one-half to three-fourths of an inch in length. The opening in the endocardium seemed about one-half as long as the external wound. A traction suture of chromicized gut was then rapidly passed through both edges of the wound and the heart held firmly up against the pericardial opening. Then four other sutures of chromicized gut were introduced with an intestinal needle. The traction suture had been put in with a spear-pointed needle and there was considerable oozing from the punctures. This I controlled with an additional suture passed with an intestinal needle. The traction suture was of the greatest aid in the passage of the others, and without it it would have been very difficult to have closed the wound, as the heart muscle was continually contracting and expanding. I made no effort to avoid the endocardium in passing the sutures, as I think it is more important to close the wound throughout the thickness of the heart wall than to avoid entering the endocardium. A small gauze drain was placed against the line of heart sutures and brought out through the pericardial opening in which no sutures were placed. In order not to prolong the operation I simply packed the external wound also. The patient went off the table in very satisfactory condition. Pulse 88, respiration 32. The pleura was not injured and I was careful to avoid it in my manipulations.

Postoperative History.—During the subsequent twelve hours there was considerable serous oozing, requiring a change of dressing. At this time the patient's pulse was 112, respirations 36 and temperature 101°. He complained of considerable pain in the left shoulder and chest. The second day after the operation his condition was quite alarming; respirations were 62, and he complained of great distress in the chest. I changed the dressing at this time and found that the gauze packing had become so dry and adherent to the wound as to interfere with drainage. I withdrew the gauze, and a large quantity of fluid from the pericardium escaped with a gush. A smaller gauze drain was introduced and a moist dressing applied, in order to insure drainage. The patient was immediately relieved and the respiration fell to 38 within a short time. Large quantities of salt solution were given by the rectum and were readily absorbed. On the second day the patient took liquid food with relish. Except for the distension of the pericardium, due to faulty drainage, the patient made an uncomplicated recovery. The dressing was changed every other day, and on each occasion for some time the pulsating heart could easily be seen. On August 5, six days after the operation, I introduced several catgut sutures into the external wound and closed it nearly completely, but no sutures were put in the pericardium, the wound in this structure having nearly closed.

On August 7 the pericardial wound had entirely closed. On August 10 the man sat up in bed, and August 13 he was out of bed. On August 19, twenty days after his operation, he was discharged with a superficial granulating wound. On September 10 he returned to work as a master plumber and tells me he has not lost a day since. At the present time he is perfectly well, and has not the slightest discomfort or pain about the wound. His heart action is regular and normal.

In reviewing the symptoms in this case it will be readily seen that they were those of compression of the heart and not those of simple profuse hemorrhage. The unconsciousness, the embarrassed respiration, the absence of pulse, the cyanosis, the feeble and irregular heart sounds, together with the increased cardiac dullness, indicated plainly compression of the heart due to hemorrhage into the pericardium. The absence of signs of fluid in the pleura indicated that this membrane had escaped injury. I think that it is important to determine, if possible, before operating for wounds of the heart, whether or not a wound of the pleura has taken place, since it may influence the choice of the method of exposing the heart. In neither of my cases was the

1. Amer. Jour. Med. Sciences, September, 1904.

2. Phila. Med. Jour., Nov. 1, 1902.

pleura injured. In the first case, however, I produced a small wound of the pleura in resecting the cartilage; I was able to avoid this complication in the present case. Unless one is able to demonstrate a wound of the pleura I do not believe that it is wise to make the osteoplastic flap which is generally recommended, but think that it is better to separate the periosteum and to excise as much of the cartilage, sternum or rib as may be necessary to give free access to the wounded heart. In the present instance, I had ample room and after the introduction of the traction suture had not the slightest difficulty in closing the heart wound. Two fingers behind the heart are quite enough to lift it up where it can be plainly seen, and the traction suture introduced. After the introduction of this suture the rest of the operation is easy. In making the osteoplastic flap it is very difficult to avoid injury of the pleura. In but a few reported cases has this structure escaped injury.

I shall be careful in my next case, if I am fortunate enough to have another, not to use any other than a curved intestinal needle, as the beveled needles produce considerable hemorrhage. I think, also, in a future case I shall not drain the pericardium, but shall close it at once, since it has been shown that after complete closure it does not become distended with fluid. The accumulation in this case was probably due to the irritation of the heart surface by the gauze which I employed. Drainage of the external wound, however, I believe should always be employed. A large percentage of the patients who have been operated on for penetrating wound of the heart have died from infection, and in a considerable proportion of those who have recovered the cure has taken place in spite of infection. I expected suppurative in this case, as there was little opportunity to sterilize the skin thoroughly, and I was agreeably surprised that the wound entirely healed without the slightest infection. The temperature chart shows the highest temperature which the patient had was 101° on the day after operation, and that after a few days the temperature remained normal.

It is remarkable that although the first successful operation of stabwound of the heart was done in 1896, less than ten years ago, there have already been reported about 100 cases, and the percentage of recovery has been surprisingly high. Dr. F. T. Stewart, in a paper which he read before the College of Physicians in May, 1904, and in which he reported a successful case, showed a collection of sixty cases with a recovery rate of nearly 40 per cent. Since his paper was published there have been a number of successful cases reported by foreigners, but I have been able to find no successes reported by American surgeons. If I am correct in this, the case which I report is the fifth successful one in this country.

This subject was so freely discussed at the meeting of the college, to which I previously referred, that I hesitate to go more deeply into the question of statistics and technic. Before closing, however, I would state that there are constantly reported cases in which patients have lived for a number of hours or days after stab wounds of the heart, a correct diagnosis not being made until after death. Whenever there is a question of wound of the heart an exploration should be made, just as it is made in questionable wounds of the abdominal wall. Too vigorous stimulation, such as the intravenous injection of salt solution, is to be strongly condemned in these cases until after the heart wound has been closed, and even then should be employed with caution.

TETANUS FROM BLANK CARTRIDGE WOUND IN A BOY'S RIGHT HAND.*

J. NOER, M.D.
STOUGHTON, WIS.

History of the Case.—E. A., aged 12, was shot in the palm of the right hand by a blank cartridge June 26, 1905, and came at once to my office. I found a small wound in the palm of the right hand between the second and third metacarpal bones. The immediate area about the wound was infiltrated with a 2 per cent. cocaine solution, a free opening made in the skin, the interior thoroughly curetted, washed out freely, and saturated with tincture of iodine compound. A gauze drain was introduced and a light gauze dressing applied.

June 27: Wound dressed and drain saturated with iodoform introduced.

June 28: Some tumefaction on back of hand. Patient put under chloroform and a free counter opening made on back of hand and an attempt made to follow up and to clean out more thoroughly the track of injury made by the cartridge. Wound thoroughly washed with hot sublimate solution, peroxid and compound tincture of iodine, and then loosely packed with iodoform gauze.

From this time wound was dressed daily, washed with hot sublimate solution and peroxid and a gauze drain introduced between metacarpal bones. This treatment was kept up till July 8, when the drain was removed and the wound allowed to close, which it did in about three days.

Patient did not at any time exhibit any symptoms of sepsis, e. g., fever, pain, glandular swelling, and increased pulse rate.

Up to July 8 he was at all times in perfect health, except the slight annoyance from the dressing and open wound in the hand. During the first week there was some slight swelling of the hand and evidence of slight pus infection, which promptly disappeared.

Tetanus Development.—July 10: Fourteen days after injury and 2 days after removal of gauze drain he complained that his back pained him some and that in the night he had had some pain in the right side below the axilla. He attributed the pain in the back to the fact that he had been at work pulling weeds the day before. It was somewhat soothing to accept the little patient's explanation of the cause of his spinal pain, but what was to be done about the decided myalgia or whatever it might be in the right axillary region? At the first visit my patient suggested the possibility of tetanus. Were his fears to become true?

July 11: I saw patient at his home. He had had a bad night and did not feel well enough to be up. Temperature, 101; pulse, 100. Right hand painful and also pain in back along spine and on right side of chest along ribs up as far as the axilla. On movement, arm was painful. Muscles of the right arm, forearm, hand and fingers showed painful spasmodic contractions every two to five minutes. Duration of spasm was very short—two or three seconds possibly. There was no trismus or other clonic contraction. There could, however, be no question about diagnosis.

Treatment.—Antitetanic serum not being obtainable in city, it was wired for, but for some unaccountable reason was not sent till next morning, causing delay of 20 hours before first injection of 20 c.c., sixteen days after injury.

Locally, nothing was observable to indicate the serious nature of the infection. The original wound was healed and nothing abnormal was in evidence, except a scar in palm and on back of the hand. Inasmuch as the tetanus bacillus is strictly anaerobic and its activity localized in the tissues at or near the point of infection it appeared rational to anesthetize patient again, open wound thoroughly, saturate with tincture iodine and drain. This was done at once.

Hydrate of chloral was given internally, one gram every three to six hours. Its administration made the muscular contractions less frequent and less severe. A hypodermic of morphin, $\frac{1}{4}$ gr., during the evening made the contractions less painful.

* From paper read before the Central Wisconsin Medical Association, Madison.

July 13: Patient shows effect of chloral and morphia by marked drowsiness. Says he feels well, except when pain comes on. Contractions come on at pretty regular intervals in all muscles of the right side of the body, beginning always in the hand, passing up the arm and thence over the right side till they involve the back and at times the left leg, producing complete opisthotonus. Intervals are longer—5 to 10 minutes—but spasms are at times very severe and painful, so much so that patient screams loud and sharp when the spasm comes on. Temperature, $101\frac{1}{2}$; pulse, 90. Hand dressed and 20 c.c. antitetanus serum injected into muscles of the back. Chloral continued and morphia, $\frac{1}{8}$ gr., given in the morning and evening.

July 14: 8 a. m., pulse 88, temperature 99. Night fairly comfortable. Had some very severe general convulsions between 10 and 12 o'clock in the night. Nurse states that face turned blue and that several convulsions were so severe as to throw him out of the bed. Chloroform had to be given to dress hand. Ten c.c. antitetanus serum was injected into back and into tissues about wound.

July 15, 16, 17 and 18: Symptoms continued about the same, except intervals between convulsions were somewhat longer—15 to 20 minutes—and patient would at times rest from $\frac{1}{2}$ to 1 hour without any painful contractions.

July 16 and 17: Patient apparently much better. Is less sensitive to extraneous disturbances, as noise and light. Hyperesthesia of skin not so marked. For days the skin was so sensitive that a breeze of cold air or a sudden touch on the skin of the hand or back would invariably produce a convulsion. Convulsive seizures are shorter in duration and not so painful. The use of morphia discontinued and chloral given only every six hours and dose lessened about one-third. While the convulsive seizures are in general much less severe and farther apart, he would have several very severe seizures during the 24 hours. These would invariably start in the right hand, passing up the arm, involving, in regular order, muscles of the arm, shoulder and back till complete rigidity with opisthotonus was produced.

The milder attacks were momentary and would involve only the right side, often only arm and back. Often patient would only complain of being too hot. There would be a momentary restlessness and the "spell" was over. The face has the characteristic expression of *risus sardonius*. Muscles of lower abdomen hard and board-like. All the muscles of the right arm, shoulder and along right side of spine are in a state of clonic contraction. The arm is flexed at the elbow, as is also the hand at the wrist and likewise the fingers.

Notwithstanding the permanent contractions of the muscles above mentioned and the occasional severe convulsive seizures, the patient was apparently much better. Pulse and temperature were normal, appetite and digestion excellent and general condition fairly good. The chloral was gradually discontinued during the next two days.

July 20: Patient had several severe and protracted convulsions in the night. Chloral was again given in gram doses, every three hours, till symptoms again abated, when interval of administration and dose was again diminished.

July 25: Convulsive seizures limited to two or three in twenty-four hours. By July 29 they practically ceased and chloral was given only three or four times in the twenty-four hours, being discontinued entirely during the following three or four days. Gauze drainage discontinued and wound permitted to close.

For a period of about 3 weeks the patient took from 2 to 5 grams (30 to 75 grs.) of chloral a day. On withdrawing it I found that he had acquired the chloral habit and it took about two weeks to wean him from it. The contractions of the muscles of the fingers, hand, arm and shoulders persisted for several weeks, but gradually disappeared by use of massage and warm baths.

Recovery in this case can, I think, be attributed to the following causes:

1. The mildness of the original infection or an unusual resisting power on the part of the patient.

2. The aid of the thorough mechanical cleaning and free drainage of wound.

3. The abundant use of chloral hydrate to control convulsions, to ease the muscular rigidity and to induce sleep.

The antitetanus serum may have aided to some extent the natural protective powers of the patient. I doubt very much if it had in this case any real curative value.

New Instrument

AN IMPROVED NIPPLE-SHIELD.

J. MORRIS SLEMONS, M.D.

Associate in Obstetrics, Johns Hopkins Medical School
BALTIMORE.

The ordinary type of nipple-shield is so frequently unsatisfactory in cases where such an appliance is urgently needed that I have designed a new model to overcome some very obvious defects in the old one.

It very often happens that the shield now on the market can not be used at all, and, indeed, in most instances where it is used there is considerable discomfort occasioned either the mother or the child. The mother must invariably assume an awkward position in order that the milk may flow in the proper direction. If in bed she must turn so that she lies practically over the child; if sitting up she must bend forward

at a very uncomfortable angle, otherwise the milk will remain in the shield. The child not infrequently is restless and dissatisfied because it is compelled to nurse so long before any milk reaches it. This is due to the fact that the rubber nipple is at a higher level than the bottom of the chamber into which the milk is first received. As a result of this a teaspoonful or more of milk must always be drawn out before the child gets a drop. Nurses, I find, have recognized this and are prone to put milk in the shield before placing it on the breast. Clearly, this is a troublesome and inadvisable procedure.

The model which I have devised is shown in the accompanying diagram. It is so constructed that the first milk drawn from the breast reaches the infant immediately. The breast nipple projects beyond the angle (marked A) in the floor of the shield and the milk falls at once through the glass tube to the rubber nipple. Delay in the transmission of the milk is entirely avoided and can not be a source of annoyance to the infant. Moreover, the S-shape curve of the shield allows the mother to be in a more comfortable position than is possible with the old model. Whether lying down or sitting up the posture required when the new model shield is used is the same as when the child is nursed directly from the breast.

The pattern presented here was devised some months ago when I found the old style appliance of no help to me in a case where the need of a shield was imperative. It worked very satisfactorily at that time and has been used since with equally good effect.

SPECIFIC SERA AGAINST INFUSORIA.

Notwithstanding the importance of many animal parasites in the production of disease, comparatively little of immunity in connection with this class of organisms. experimental work has been done from the standpoint. This is evidently due to the fact that it is difficult to obtain cultures of such organisms. That immunity is an important factor in diseases of protozoan origin is clear from the fact that in malaria an acquired immunity may be developed, as is also the case in Texas fever. The best known experimental work along these lines is the immunization of rats against trypanosome infection. Rabinowitch and Kempner treated white rats with the blood of gray rats infected with trypanosomes and succeeded in producing an immunity in the former. Laveran and Mesnil, in investigating the properties of the immune blood serum, found that it was not trypanocidal, but possessed an agglutinating property without destroying motility. When injected into the peritoneal cavity the trypanosomes were not changed morphologically, but were soon taken up by the phagocytes and digested. All attempts by these workers to isolate a specific toxin by heating, drying or freezing the organisms failed, and growing them in collodion sacs in the peritoneal cavity of animals gave no evidence of the production of a toxic body.

An important paper by Rossie¹ recently appeared, in which the author gives his results of immunizing animals with infusoria. *Paramecium caudatum* and *Glaucocoma scintillans* were injected several times subcutaneously into rabbits and guinea-pigs and the properties of the serum of these animals were compared with normal serum. Since normal serum in pure condition is injurious to the organisms it is necessary to work with diluted sera. At a dilution of 1 to 20 or higher no effect is noted by the normal serum on the infusoria. The immune serum, however, behaves very differently. The infusoria when introduced at first swim about in a very lively manner; this activity soon ceases and there follows a specific toxic effect in the form of a paralysis of the paramecium, involving the cilia of the surface, the contractile vacuole and finally the undulating membrane of the ectostome. A distinct agglutination does not occur, but the organisms tend to adhere to the sides of the container and other objects, but not to each other. No anatomical changes could be made out nor anything

that could be interpreted as a lytic process, though certain differences could be brought out by vital staining between the protozoa treated with the normal and the specific sera. The fact should be noted that in low dilutions the same effect was observed in the normal serum as in the specific serum, there being therefore not a qualitative, but only a quantitative difference between them. The immune serum lost its specific properties by heating at 56 C. for one hour and could not be reactivated by normal serum. A curious result was obtained by using Loeffler's method of immunizing with the dry heated bodies of the paramecia. Obtained in this way, the specific body of the immune serum was much more stable, resisting a temperature of 70 degrees for one-half hour, but in other respects agreeing with the serum prepared by the injection of living infusoria.

Probably the most interesting and important observation made was the following: If the organisms were introduced into the specific serum for a time, then removed and washed, and after a time again introduced into the serum, it was found that they were less sensitive to the specific effect, and by continuing this process the organism finally reacted to the specific serum in the same way as to the normal. In other words, the infusoria themselves had become immunized against the specific serum. It is possible, or rather probable, that protozoa which cause disease may thus immunize themselves against the body juices in this manner, and Rossie calls attention to the possibility of this occurring in these diseases; and this may be an explanation of the protracted course and the incurableness of many of the protozoan diseases.

These facts, indicating an immunization of the invading organism against the body fluids, are exactly in accord with the hypothesis advanced by Dr. Welch in the Huxley lecture in 1902. He called attention to the possibility of the living bacteria in the host casting off receptors as a result of the stimulation of the body cells, and to the possibility that there may thus rise from bacteria lytic bodies which act specifically on the various cells of the host. The conception is made clear by considering the bacterium as the host and the cells of the body as the invader. The bacterium would thus acquire an immunity against the cells or the body fluids.

In calling attention to this work it should be noted that the author so far has only worked with a few animals, and, therefore, many more experiments must be made before the results given above can be accepted beyond question. The few results obtained are so suggestive, however, that work with this class of animals should be vigorously carried on. The author has devised some very clever means for obtaining the infusoria in pure growths, meaning by this growths of one variety of infusoria, but not free from bacteria, there being always some of the latter of a harmless character in the cultures used. These do not interfere with the inoculation experiments. For the details of these methods the original work should be consulted.

¹ Arch. d. Hygiene, vol. III, p. 1, 1905.

LYMPHATISM AS A FAMILY DISEASE.

As medicine grows older there is a tendency to discard some of the terms formerly used as being either inaccurate or unscientific. In some instances, a term, such as *scrofula*, has been rightly discarded, because it covered a variety of conditions, due to a variety of causes, and clinically separable. In other cases, terms have dropped into disuse because they were unfashionable or because it seemed that the condition they described was not scientifically proved to exist. Among this last group must be mentioned the so-called diatheses and temperaments about which our professional grandparents were so fond of speaking and which we so rarely mention. We probably tend nowadays in some ways to be too scientific, to discard terms too easily because we can not show actual pathologic evidence that they exist, forgetting that there are many conditions undoubtedly existent, of the pathology of which we are still ignorant. Among the diatheses, the lymphatic diathesis is the only one which seems at present to be on a firm anatomic basis.

We have mentioned before the condition spoken of as lymphatism or the status lymphaticus. It is far from uncommon, and from its association with sudden and mysterious deaths in infants has a medicolegal aspect, as well as a strictly professional one. It will be remembered that children who present this condition of lymphatism are unusually subject to infectious diseases, as is also true of the small proportion of adults who are affected, and that in quite a large proportion of the cases of death from anesthesia the condition is present. Some of the curious cases of death following trivial physical shocks or even fright have also been shown to be associated with the status lymphaticus.

The fact that this condition may exist as a family disease so far has not been especially emphasized, and it has remained for Hedinger¹ to call attention to this aspect of the question. In his article he mentions a family of nine children, five of whom had died suddenly during infancy. In some instances, the child simply became cyanotic, lost consciousness, and was dead in a few minutes. In other cases, the picture was that long ago described by Kopp as thymic asthma. Hedinger cites reports of a number of other observers recording the death under similar circumstances of from two to nine children in single families.

The lesions found in such cases are constant, though varying in degree, and consist of enlargement of the thymus and of the lymphatic apparatus, the latter sometimes affecting single groups of glands, but more often involving also the lymphatic apparatus of the spleen and the intestines. The microscopic lesions resemble in many ways those of an infection, though bacteriologic examination is usually negative.

The pathogenesis of this condition is still very obscure and seems liable to remain so. There is nothing known

to account for its appearance in several members of a family. Alcoholism in the parents and consanguinity have both been blamed for this as for many other family conditions. The conditions found, as stated, suggest infection, and the possibility of an autotoxemia has been suggested, but merely on the ground of the histologic resemblance of the lesions in this condition to those of bacterial infection. Possibly some curious change in metabolism, a subject about which we still know so little, is at fault. For the present we must be satisfied with knowledge of the occurrence of the condition and look to the future for an explanation of its cause.

MEDICAL HISTORY ERRORS.

Few things have been more encouraging in recent medical literature than the renewed attention which is being paid all over the world to the history of medicine. Nothing is more chastening than to find how many of the discoveries that are thought to be very modern are only re-discoveries of the principles that were discussed by men many centuries ago, practically applied in their teachings and in their practice and then forgotten because of changes in the theoretic point of view in medicine. Another interesting phase of this subject has been the larger sympathy that has developed for these early workers in medicine and the realization of how much they accomplished and under what apparently discouraging circumstances. Indeed, until recently, when the works of the old masters have been more read, the old-time medical curricula in the universities were so little understood that it was considered that certain phases of scientific medical work were not touched on at all.

Perhaps the most striking example of this is to be found in the impression conveyed by practically all histories of medicine published in English that during the fourteenth and fifteenth centuries there was little or no development of the science of anatomy in Christian Europe because the practice of dissection was under ecclesiastical censure. The supposed decree by which this fatal obstacle to anatomy was created was pointed out very definitely, and it seemed to be clear that it had prevented all dissection. As a matter of fact, however, the history of the fourteenth and fifteenth centuries shows a continuous series of anatomic developments of high order, in spite of the supposed papal legislation against it. Further investigation shows that the decree which was supposed to have forbidden dissection really forbade quite a different practice and on very justifiable grounds. Pope Boniface VIII prohibited the crusaders from cutting up the bodies of their dead friends in the East and boiling them in order to bring the bones home for burial in Europe. It is easy to understand how many serious evils might follow from this unhygienic practice and how eminently commendable was the promulgation of this law. It seems especially unfortunate that it

should have been misconstrued into an attempt to prevent the development of the science of anatomy along the only lines in which such development is really possible—those of actual dissection and practical demonstration.

An examination of the decree itself brings out these facts very clearly and the history of anatomy in the centuries immediately following this promulgation shows the rest. Within a few years after the issuance of the decree Mondino did his great work in dissection in Italy and published a text-book which was the guide for dissectors for nearly two centuries. A corresponding state of affairs has recently been shown to exist with regard to the false impression that alchemy, the mother science of chemistry, was also forbidden by the ecclesiastical authorities. Investigation proves this second supposed decree hampering the development of the great science to be quite as much misconstrued as that with regard to anatomy.

"Alchemies" were forbidden, but it is clearly stated just what chemical processes were intended by the word alchemies. Many of the alchemists pretended to make gold and silver and found a number of dupes who were quite content to give them real gold and silver for the supposed precious metals that they could manufacture. Alchemies of this kind were forbidden, but nothing else. The pope¹ who issued the decree was himself one of the most earnest students of chemistry of the time, doing excellent original work, and published a volume in which he demonstrated the impossibility of the transmutation of metals. Professor Allbutt, in his address on the historical relations of medicine and surgery at the Congress of Arts and Science held at St. Louis in 1904, mentioned a little book on eye diseases written by this same pope, John XXII, which contained some very practical directions in regard to the treatment of ordinary affections of the eye.

The general histories of medicine published in English still continue to repeat these erroneous statements with regard to ecclesiastical interference which did not take place. As a matter of fact, the whole attitude of the ecclesiastics of the time was in favor of the development of scientific teaching of all kinds and they were prominent in their encouragement of universities. The grateful acknowledgment of what was accomplished within these earlier ages and the recalling of it to modern generations will only make clear how slow is human progress and how much even the best advances are likely to sink into obscurity if they are neglected for some passing favorite theory. This of itself should be enough to bring us to do justice to the grand old men of the golden times who accomplished so much with inadequate means, and often under discouraging circumstances, for the development of the sciences whose full fruition was thus delayed for so many centuries.

THE SO-CALLED MAGIC TOUCH AS OPPOSED TO LABORATORY PRECISION IN DIAGNOSIS.

Regretful surprise is occasioned whenever a respected contemporary lends its support to the minority protest against the revolution in pathology, diagnosis and therapy which laboratory science has effected in medicine during the last three decades and which, as every liberal-minded physician knows, is still on the very threshold of its achievements.

Innovation has always had its obstructionists, reform its opponents. A few years ago a surgeon of prominence, for motives best known to himself, publicly decried the value of laboratory methods as applied to surgical diagnosis. He found a sympathetic audience in those who, for lack of knowledge or from inertia, had been unable personally to acquire the skill and knowledge necessary to apply these methods in their daily work. He attained a notoriety of advertising proportions. Privately, however, this surgeon was forced to admit that he availed himself of many of the laboratory's results in deciding the nature of a given surgical affection. Like all appeals to prejudice, however, his utterances were accepted as sincere and his cue was followed by many imitators. Thus an agitation against laboratory aids in diagnosis was launched.

An amusing feature of this really ridiculous campaign is the constancy with which its advocates are compelled to fall back on their plea for an education of the senses as the *sine qua non* of diagnosis. A recent flowery orator proclaimed to his audience that he taught his students the importance of training the sense of touch, and thus enabled them to render superfluous the microscope, test tube, microtome, culture media, blood-counting apparatus, centrifuge and all the other paraphernalia of the modern diagnostic laboratory. These men forget that our medical forefathers educated their senses to a degree of acuteness unattainable by modern men who have perfected various implements like the stethoscope, ophthalmoscope and fluoroscope to assist the senses which have long since depreciated through various agencies of civilization.

This appeal reminds one of a kind of retrogression in which a premium will be placed on the magic touch, or the laying-on of hands of medievalism, or the persuasive, pocket-emptying "touch" of osteopathic or other manipulating quacks. These pleaders for sense-education seem to forget that good laboratory practice is the most effective training for sharpening the senses, and that it scores its triumphs in the sickroom whenever a laboratory worker chooses to enter the pursuit of clinical medicine or surgery.

To give a detailed account of the achievements of the laboratory in forwarding medicine is a task so laborious as to exhaust one's patience when called on to controvert the claims of those antagonizing progress in this direction. Instances in which the theory and practice of medicine have been revised and uplifted through the

¹ John XXII and the Supposed Bull Forbidding "Chemistry,"
J. A. Walsh, Medical Library and Historical Journal, vol.
1, p. 1.

conquests of the laboratory, if enumerated, would pass in review the history of medicine in the last three decades, an era of progress beside which all former periods attain utter insignificance. And this is due not to better training of man's senses, but to the aid these senses have secured through laboratory devices.

THE STATE AND TUBERCULOSIS.

In the present medical and public enthusiasm in regard to the tuberculosis question the duty of the state has been a subject of much discussion, which has in turn led to a considerable amount of actual and proposed legislation. Some of this has been wise, part of it might be wiser. A very fair and sensible review of the subject is given in an address delivered by Dr. J. P. C. Foster¹ of New Haven, Conn., before the Laennec Society of Johns Hopkins Hospital. The measures which he points out as necessary are the scientific supervision of water and milk supplies, rational tenement-house legislation, registration of cases of tuberculosis, control of indiscriminate expectoration, and proper efforts to educate the public in needed sanitary precautions. His remarks in regard to the last named necessity are pertinent and suggestive. He recognizes that there is a tendency to overdo the matter of expense in sanatoria and public care. "The highest claim," he says, "that such institutions have on state support is not in their charitable, but in their educational value."

Even with the model of the Massachusetts State Sanitarium before him he does not seem positive as to the advisability of erecting state institutions. The better way, as he sees it, is in the formation of state anti-tuberculosis associations, which, through private benevolence, should initiate and control the sanatorium movement, and only ask a certain amount of government aid when the usefulness of the institution is assured. This is the plan which has been adopted in Canada and, to a certain extent, in his own state of Connecticut. There will be no lack of private benevolence when the need for it is definitely shown, and it is not necessary that such institutions should be unduly multiplied or expensive. He would make a sanatorium of this kind meet the needs of a population of not less than 250,000, and its work should be mainly educational. It is neither necessary nor desirable that these should be free institutions, but they should receive curable indigent patients of special intelligence who could serve as sanitary missionaries after their discharge.

The vast army of indigent and ignorant consumptives should receive proper care in municipal institutions, in which, if necessary, they could be isolated without causing undue expense. The average consumptive in private life needs education rather than isolation or public care. The intelligent and organized effort that is required properly to bring about the best results is clearly indi-

cated in Dr. Foster's address, and as an object lesson he related what has been successfully done in New Haven and Hartford, where, with an expenditure of only \$50,000, provision has been made for 100 beds, fully one-half of the number for which the state could justly be called on to contribute, and this absolutely without any political work or interference whatever.

THE SEVENTEEN YEARS' WAR FOR PURE FOOD.

The history of the pure-food legislation and the methods and the motives of its obstruction by the Senate are well described by Henry Beach Needham in the *World's Work* for February. He shows that the first pure-food bill was introduced seventeen years ago into the Senate, and that during the past four years substantially the same act has twice passed the House. The obstructive tactics of certain senators and the motives of the leading opponents of the bill are pretty well analyzed. The liquor interest, the patent-medicine business, the cottonseed oil industry of the South (which furnishes most of our imported olive oil) glucose manufacturers, etc., all have their advocates among the Senate leaders, one of the most prominent of whom, who is said to have much control over legislation and to be himself interested in the wholesale grocery business, a fact which "senatorial courtesy" does not allow being mentioned in the Senate debates. He points out that the tactics in the present long session are likely to be somewhat different from those that prevailed last year. If, he says, public clamor shows no signs of abatement the Senate "yields." When the Senate yields, then is the time to watch legislation, for while obstruction is still practiced the chief reliance is on emasculation. "To convert a bill drawn in the interest of the whole people into a harmless measure which 'business' will accept" is then the policy. "Beware of the Senate when it 'yields,' for it has not yielded. The enacting clause of the House bill will be retained, but the remainder of the measure will be the Senate's own make." We must not give the matter up. There is a force of public opinion that can make the Senate yield to some purpose, and the medical profession should have its share in creating it.

TETANUS FROM BLANK CARTRIDGE WOUND.

For several years in our annual Fourth of July tetanus article we have laid particular stress on the necessity for the most vigorous measures in the treatment of blank cartridge wounds when first seen by the physician, and also the prophylactic administration of tetanus antitoxin. The radical nature of the procedures we have advocated, namely the anesthetizing of the patient and most extreme dissection and drainage of the irregular radiating track of the explosive injury, have seemed to many unnecessary. Until one has proved it by dissection it is hard to appreciate how widespread are the effects of the explosion beneath the skin, and without this appreciation it would seem possible to secure adequate cleansing and drainage by fairly free incision and the usual surgical measures. The administration of antitoxin as soon as possible after the injury is received has seemed

1. Published in the Johns Hopkins Bulletin and Charities and the Commons simultaneously.

to many an unnecessary elaboration of the prophylactic measures. Elsewhere in this issue¹ is narrated a case that seems to us to corroborate the position we have assumed. The patient, with the usual blank cartridge wound in the hand, was given exceptionally thorough surgical care under local anesthesia, including thorough curetting and the use of iodine as an antiseptic. Two days later the wound was again cleaned out, this time under general anesthesia, and from that time until it had healed up it was treated most thoroughly under the best surgical methods. Yet in spite of all this care, tetanus developed on the fourteenth day. We agree with the reporter of the case in ascribing the successful outcome to the thorough mechanical cleaning and free drainage of the wound, which undoubtedly tended to make the severity of the infection much less than it would have been under less vigorous treatment. At the same time it emphasizes the fact that tetanus is not an ordinary surgical infection that can be met by the same methods of treatment that are successful in preventing infection with other organisms. As in this case, infection with other bacteria may be avoided, and healing take place aseptically, but deep in some hidden corner the tetanus bacilli or spores may hide, uninjured by any antiseptics that may reach them, capable of multiplying and killing the patient at the first favorable opportunity. If thorough surgical treatment is instituted with every such injury the incidence of tetanus as a Fourth of July sequence will be enormously lowered, but to secure the final complete success it is necessary to go beyond ordinary surgical methods and to administer a prophylactic injection of antitoxin—only in this way can we make sure of avoiding tetanus altogether.

ANOTHER STEP TO PROTECT CHILDHOOD.

As the result of an interesting trial three Chicago saloon-keepers were recently ordered to pay \$17,500 damages to some children for injury done them by reason of the repeated intoxication of the father through liquor sold by the saloon-keeper. The law which recognizes the principle that a liquor seller, in selling or giving intoxicating liquors to a habitual drunkard, injures the person, property and means of support of dependent children has in it possibilities of much good. An important social problem of the dependent in our cities is vitally connected with intemperance, and every influence is needed which can be brought to bear on this etiologic factor. We have to provide hospitals, asylums and agencies of relief to repair the damages done to individuals and to society, and more verdicts such as the one above referred to would have the double effect of checking the cause and of relieving the result.

ANOTHER JUDGE DEFINES PRACTICE OF MEDICINE.

We are privileged to add to the collection of erratic definitions of the practice of medicine one by Justice Joseph M. Deuel, who remarks that the practice of medicine consists of three things—diagnosis, discovery of the cause, and the cure by drugs, and that if a doc-

tor does not prescribe drugs he is not practicing medicine. *American Medicine* very brightly remarks: "This must be wormwood and gall to the therapeutic nihilists, and it should stimulate our pharmacologists and therapeutists to renewed activity in their efforts to restore their special science to its at one time pre-eminence. In the meantime, the surgeon who reduces a dislocation and the physician who cures a tuberculous patient with cold air and good food, are not in the practice of medicine at all. It is difficult to comment temperately on such a blow at the medical profession; indeed, it is not possible to follow out the mental processes which result in such a conclusion." We may call attention to the fact that some light is thrown on the mental processes of the judge by the fact that he is the one whose character and practices were laid bare by the exposures in the recent libel suit in which *Collier's Weekly* was vindicated for its attack on the vile *Town Topics*.

BRITISH CONTROL OF MISCONDUCT.

The British General Medical Council, the central body of which regulates medical practice in Great Britain, has issued a notification that any practitioner who resorts to advertising and canvassing methods renders himself liable to be charged under the medical act with "infamous conduct in a professional respect" and with erasure of his name from the register of local practitioners of medicine. The phraseology has an ugly sound, but it seems to us to fit the offense. Unfortunately in this country not all our state boards are legally qualified to follow this British precedent. There are without question many illegal advertising quacks in Great Britain, but it is a satisfaction that they are legally infamous as such, and their social and business standing must be more or less affected, even if their activities are not entirely squeaked. It does not take much search of the advertising columns of the secular press in this country to find plenty of evidence of "infamous" quackery in every sense of the word. We wish that the British rule could be enforced here.

THE SPITTING HABIT.

In spite of the rather spasmodic enforcement of anti-spitting regulations, there are some valuable results of the agitation. Many spitters have been led to see themselves as others see them and have reformed to a certain extent. The promiscuous spitting that used to be common in cars and in public places is certainly lessened and the improvement is still progressing. A Rochester (N. Y.) paper says that the educational effect of the agitation has been marked in that vicinity. The work of the enactments, so far as they have been made, has been mainly educative, the few instances of their enforcement serving mostly to point a moral. There is a certain class of mankind to whom only penalties will appeal, but for the great mass of approximately decent people the agitation of the subject is constantly being more and more effective. The bad habit of spitting in public places bids fair to be before long a thing of the past.

Medical News

ALABAMA.

Personal.—Dr. Lucian A. Spencer, Bessemer, was severely injured January 13 in a collision between his buggy and a delivery wagon.

Doctor's Office Destroyed by Fire.—On January 17 fire originating in an adjoining building destroyed the office of Dr. Samuel C. Tatum at Center. The damage is estimated at \$200.

Society Elects Officers.—At a meeting of the Dallas County Medical Association, held in January, the following officers were elected: President, Dr. William W. Harper, Selma; secretary, Dr. Barney B. Rogan, Selma; treasurer, Dr. Clement Ritter, Selma, and censors, Drs. Samuel G. Gay, Clement Ritter, W. McLean Pitts, William W. Harper, all of Selma, and Dr. Joseph M. Donald, Harrell.

DISTRICT OF COLUMBIA.

Personal.—Dr. S. O. Richey, who has been ill for some time, has returned to the city fully restored to health.—Dr. William R. Moulton, formerly resident physician at Bilibid prison, Manila, P. I., has returned to Washington.

Health of the District.—The report of the health officer for the week ended January 20 shows that there were 118 deaths, 67 white persons and 51 colored. The following cases of contagious diseases were reported: Diphtheria, 38; scarlet fever, 35; typhoid fever, 56; smallpox, 20.

Health Employes to Take Vacations in Winter.—Dr. William C. Woodward, health officer of the district, in his report to the commissioners, states that the natural desire of the employes of the department to take vacations during the summer months interferes with the work of the department. He advises either dividing the vacation period into two terms, only one of which may be between June 1 and September 30, or allowing employes to take the entire vacation of thirty days during the winter months.

ILLINOIS.

Illegal Practitioner Sentenced.—"Prof." J. R. Braun, Hillsboro, charged with violation of the medical practice act, was found guilty January 24 and sentenced to pay a fine of \$100 and, in default of payment, was committed to jail.

A New Society.—The Eastern Illinois Ophthalmological and Otological Society was organized at Champaign January 16. At a meeting to be held in Decatur, March 6, permanent officers will be elected and the organization perfected.

Evanston Is Healthy.—The health commissioner of Evanston announces in his annual report 209 deaths in a population of more than 23,000, or a little less than 9 per 1,000. Pneumonia and heart disease each caused 20 deaths; tuberculosis, 19, and cancer and old age, each 15.

Physician Wins Suit.—In the suit of Charles Yeager, a butcher of Belleville, against Dr. Arthur M. Kohl, in which the plaintiff claimed \$3,000 damages on account of the closing of his place of business, confiscation of his stock and his own confinement in the county contagion hospital on account of smallpox with which he claims he was not afflicted, the jury returned a verdict for the defendant.

Personal.—Dr. Baker, Congerville, has purchased the practice of Dr. Eric W. Zook, Dunlap.—Dr. Reinhardt Rembe, formerly a practitioner of Bloomington, but for the last five years a resident of Munich, Germany, is spending the winter in America.—Dr. W. E. Schowengerdt, Champaign, is seriously ill with typhoid fever.—Dr. William H. Scott, Dallas City, was thrown from his buggy in a runaway accident January 23 and sustained severe bruises of the face.

Chicago.

Hospital Dedication.—The new Washington Park Hospital at Sixtieth Street and Vernon Avenue was dedicated by a charity bazaar, held on the evenings of January 31 to February 3 inclusive.

For Sick Children.—At the performance of "Babes in Toyland," January 29, the proceeds of which was given to the Children's Hospital Society at Chicago, the net receipts amounted to \$3,500.

Newberry Medical Library Sold.—The trustees of the John C. Newberry Library completed arrangements February 5 whereby the medical department of the Newberry Library will be transferred to their new building when it is completed. During the intervening time they will have charge of the immense collection in its present quarters in the Newberry Library building.

Deaths of the Week.—For the week ended February 3 the total deaths were 557, equivalent to an annual mortality of 14 per 1,000. Pneumonia caused 103 deaths; consumption, 68; Bright's disease, 42; violence, including suicide, 40; heart diseases, 39; intestinal diseases, 32, and cancer, 31.

A Banquet to Baron Takaki.—A banquet is to be given on the evening of February 10 to Surgeon General Takaki of the Imperial Japanese Navy (retired) by Dr. Nicholas Senn, at which, in addition to the guest of honor and Dr. J. J. Takamine, the Senn Club and representatives of the medical departments of the Army, the Navy, the Public Health and Marine-Hospital Service and the Illinois National Guard will be present.

Again Convicted. Dr. Francis M. Steward was convicted January 29 of robbery. Felix Barard, the complainant, stated that he was met on the street by a "capper" and invited to the office of Dr. Steward for free examination, at the conclusion of which he was informed that he had a number of serious diseases and that his bill was \$110, which he had to pay or leave his clothes. The previous conviction of Dr. Steward was for a similar offense in 1897. The defendant moved for a new trial and was released on bonds of \$6,000.

IOWA.

New Hospital.—The old Christian church at Charles City has been sold to Dr. J. H. McLeod, who will repair the building and fit it up as a hospital.

Addition to Hospital.—The new building of St. Joseph's Hospital, Keokuk, erected at a cost of about \$30,000, was turned over by the directors January 20.

Asks Definition of Vaccination.—The State Board of Health has asked the legislature to define "vaccination" as prescribed in the law requiring all school children to be vaccinated. The point at issue is whether the so-called internal vaccination practiced by certain homeopaths is or is not to be considered as vaccination.

State Inebriety Hospital Opened.—The Detention Hospital for Inebriates, Knoxville, was opened January 18. Hereafter all dipsomaniacs will be committed to this institution instead of to insane hospitals, except that women inebriates will still be committed to the State Hospital at Mount Pleasant. Dr. O. C. White has been made superintendent of the institution, and Dr. W. S. Osborne of the Cherokee State Hospital has been made assistant superintendent.

Polk County Medical Society.—This society held its annual meeting at Des Moines and elected the following officers for the ensuing year: President, Dr. A. C. Page; vice-president, Dr. G. D. DeYoung; secretary, Dr. C. A. Ayres; treasurer, Dr. Clifton Scott; censor, Dr. J. W. Cokenower. The society instructed the secretary to send a telegram to Congressman Hull endorsing the pure food bill now before congress, and requesting him to use his efforts toward its passage. A committee of three was appointed to confer with local school boards regarding sanitation in public schools. The present membership of the society represents 85 per cent. of the eligible practitioners of Polk County.

Personal.—Dr. Gay Ramsey, North Liberty, was seriously injured in a collision between his sleigh and a trolley car January 9. Dr. Ramsey's hip was badly fractured, but it is not believed that he sustained internal injuries.—Drs. B. M. Howland, Melbourne, and E. M. Singleton, Marshalltown, have been selected as physicians of Marshall County.—The office of Dr. Fox, Calendar, was destroyed by fire January 18.—Dr. N. McKitterick, Burlington, has resigned as president of the Des Moines County Medical Society.—By the will of Mrs. Jessie M. Bishop, her residence in Charles City, valued at about \$10,000, is bequeathed to her physician, Dr. A. R. Brackett.—Dr. H. S. Patterson, Elkader, has been reappointed a medical member of the commissioners of insanity.—Dr. Frederick E. Welch, Rutland, was operated on for gallstones in Mercy Hospital, Chicago, January 1, and is making rapid progress toward recovery.—Drs. H. O. Conaway, Osakeola, and J. C. Farrell, Barnes City, have been appointed physicians for Mahaska County.

MARYLAND.

New Hospital for Northern Maryland. A new hospital was opened in the northern section on February 1; it is known as St. Luke's and accommodates twenty patients, but will be enlarged shortly. The incorporators are Drs. C. K. Jump, E. Z. Cole, Charles L. Ramsey, William Dubany Thomas, George E. Hunk, John A. Evans, Bowman M. Hoad, William M. Paine-baker, O. E. Murray, J. W. Wiser, B. C. Catlin and H. H. Stansbury. Dr. William Dubany Thomas will be superintendent.

Society Elects Officers.—At the annual meeting of the Talbot County Medical Society, held at Easton January 31, the following officers were elected: President, Dr. Julius A. Johnson, Easton; vice-president, Dr. Edward R. Trippe, Easton; secretary, Dr. Philip L. Travers, Easton; censors, Drs. Kennedy Wilson, Tilghman; Samuel C. Trippe, Royal Oak; Charles H. Rose, Cordova; delegate, Dr. James A. Stevens, Oxford. There was a good attendance, and addresses were made by Drs. R. T. Taylor, Thomas Cullen and Lewis M. Allen, of Baltimore.

Baltimore.

Births and Deaths in January.—During January 906 deaths and only 735 births were reported. Several deaths from grip were reported during last week.

Course of Study to be Lengthened.—The authorities of the Johns Hopkins University are considering the question of lengthening the course in the collegiate department from three to four years and that in the medical school from four to five years.

Portrait of President Remsen for Johns Hopkins University.—A full-length portrait of President Ira Remsen of the Johns Hopkins University has been painted by his son, Ira M. Remsen, formerly a student at Johns Hopkins and now an artist in New York City. It is said to be intended as a gift to the university.

Personal.—Dr. William Osler left Baltimore on January 30 for Canada after a stay here of three and one-half weeks. He will spend several days with his mother and will then return to New York and sail for England. He read a paper at the Johns Hopkins Hospital Historical Club January 29 on John Radcliffe, who established the Radcliffe Library at Oxford in 1740.—The real and personal estate of the late Dr. Charles C. Shippen is appraised at \$164,965.

MASSACHUSETTS.

City Protests Against Pollution of River.—The city of Waltham has protested before the committee on public health against the introduction into the Charles River of sewage and waste by the manufactories and town of Milford, which is 60 miles upstream.

Brookline to Have a Municipal Gymnasium.—The town of Brookline, "the richest town in the world," has voted \$100,000 to build a new municipal gymnasium. It will be located on the square where already face the high school, manual training school and the free public bath house.

Lectures on Medical Jurisprudence.—Erza R. Thayer, LL.B., is to give four lectures on the physician's relations to the law and the courts at Harvard Medical School on Monday evenings at 8, beginning February 12. The lectures are open to medical students and to members of the profession.

Height of Buildings.—Another bill introduced in the Massachusetts legislature affecting the health of cities provides that all buildings hereafter erected outside of Boston shall be not more in height than one and one-fourth times the width of the street on which they stand and none over 125 feet high. Some such law prevails in Paris.

Boston.

Mayor Finds Fault with Milk Inspectors.—Mayor Fitzgerald of Boston has found fault with the milk inspectors employed by the Board of Health, with the result that two of them have been suspended.

Testimonial to a Trustee's Work.—A letter of hearty appreciation has been sent by sixty-nine medical men to Hon. Henry H. Sprague, a trustee of the City Hospital, accompanied by a silver bowl and platter appropriately inscribed. The letter commends Mr. Sprague's character, energy and fidelity in his thirty years' service as trustee.

Protection of Food from Contamination.—The Woman's Health Club has petitioned the State Board of Health to make regulations for protecting food offered for sale in public places from contamination. Dust, flies, odors, excrement of dogs, cats and mice, and indiscriminate handling are all shown to be real dangers, especially to the food sold to poor people.

Personal. Dr. David Cheever, son of Dr. David W. Cheever, has been appointed third assistant visiting surgeon to the Boston City Hospital. His father was one of the six surgeons first appointed to the staff of the hospital in 1861, when the institution was opened. Dr. James J. Scannell has been appointed assistant bacteriologist. The other men have moved up since the departure of Dr. H. W. Hills, and now the laboratory is in charge of B. R. Richards, S.B., assisted by Dr. Francis H. Slack.

The New England Deaconess Hospital.—Though this institution has only 14 beds, it cared for 234 patients last year, 1,763 during the ten years since it was started. Twenty-five deaconesses made 20,865 calls in the year. Of the work done one-third is gratuitous. Sufficient funds have at last been secured to guarantee the starting of the new hospital building in March. This is to be near the great group of medical school and hospital buildings in Longwood.

MISSOURI.

Alumni Election.—The Medical Society of the City Hospital Alumni of St. Louis elected Dr. L. H. Behrens, president; Dr. W. Baumgartner, vice-president; Dr. F. J. Taussig, secretary, and Dr. Jules Brady, treasurer.

Election of Officers.—The election of the St. Louis Medical Society resulted as follows: President, Dr. George Homan; vice-president, Dr. Robert Barclay; secretary, Dr. Hart Goodloe, and treasurer, Dr. Charles J. Orr.

Personal.—Dr. R. B. Gradwohl, St. Louis, announced at the meeting of the St. Louis Medical Society, February 3, the discovery of a new species of intestinal parasites, probably belonging to the *Oesophagostomum* family of the *Secerostoma*.—Dr. George Harron, at the same meeting, reported an interesting case of hookworm disease observed in Missouri, but contracted in Alabama.—Dr. and Mrs. Richard L. Sutton, Kansas City, sailed for Liverpool January 13 for a trip of two years abroad.—Dr. and Mrs. John H. Duncan, St. Louis, sailed for Europe February 1.—Dr. Guy L. Noyes has succeeded Dr. Edward W. McAlester as superintendent of Parker Memorial Hospital, the hospital of the medical department of Missouri State University, Columbia.

NEW JERSEY.

Personal.—Dr. Harry H. Pemberton of Long Branch was shot but not seriously injured by his daughter, January 29. The daughter was subsequently examined by physicians and pronounced to be insane.

NEW YORK.

Mortality in the State.—The State Department of Health reported 137,059 deaths in this state last year. These, together with 175 delayed returns, made a death rate of 17.4 per 1,000, or about the average for the past five years. There was a daily average of 376 deaths, against 380 in 1904 and 350 in 1903. Pneumonia was the chief cause of death, causing 14,157 deaths in 1905, against 13,531 in 1904, and 9,000 in 1903. Consumption caused fewer deaths than pneumonia. The mortality from cerebrospinal meningitis was 2,566, against 1,700 in 1904, the average being in former years 550. Diphtheria had the smallest mortality of any year on record. Typhoid fever had fewer deaths than in the two years preceding. Smallpox occurred in only a few localities and the nine deaths were all in the maritime district. Epidemic diseases caused 13.5 per cent. of the mortality. Consumption caused 10 per cent. of the deaths, and 175 deaths per 100,000 population in the maritime districts. The infant mortality was 27.5 per cent. of the total, being 1,000 less than last year. There were 24,000 deaths of individuals past the age of 70. Bright's disease caused 8,870 deaths; in 1902 this disease caused 6,818 deaths; in 1903, 7,674; in 1904, 9,068.

Buffalo.

Personal.—Dr. Marcel Hartwig was recently operated on at the Johns Hopkins Hospital, Baltimore.—Dr. Roswell Park, who has been confined to his home by illness, is rapidly convalescing.

Hospital Elections.—The Buffalo Emergency Hospital staff at its annual meeting elected the following officers: President, Dr. Francis J. Carr; vice-president, Dr. Vertner Kenerson, and secretary, Dr. Edgar A. Forsyth.—The Buffalo Hospital Sisters of Charity held the annual meeting and elected the following officers: President, Dr. George H. Westinghouse; vice-president, Dr. Walter D. Greene, and secretary, Dr. Alfred E. Diehl.

New York City.

Harvey Society Lecture.—The eighth lecture in the Harvey Society course will be delivered by Prof. L. B. Mendell at the New York Academy of Medicine on Saturday, February 10, at 8:30 p. m. Subject, "The Formation of Uric Acid."

Smallpox at Quarantine.—The Fabre line steamship *Roma* was detained for several hours because one of her steerage passengers was ill with smallpox. Three hundred and fifty passengers who were in the same compartment were detained at Hoffman Island for observation.

A New Catalogue.—The New York Academy of Medicine has just issued a catalogue containing the acts of incorporation, constitution and by-laws, a list of fellows, associate fellows, honorary fellows, benefactors, and a complete list of fellows from the institution of the Academy, Jan. 6, 1847, to Jan. 1, 1906.

Fire in Bellevue Laundry.—Eight hundred patients were endangered by a fire in the laundry building connected with this hospital early on the morning of January 30, but owing to the quiet and effective work of the hospital fire brigade and the city firemen only a few patients were awakened, and the damage does not exceed \$1,000.

Beginning New Bellevue.—Two brick pavilions on the southeast corner of the grounds have been emptied of patients and will be razed. This is the first step in the erection of the new hospital for which \$8,500,000 has been appropriated. The consumptive patients have been sent to the Metropolitan Hospital while the others will be cared for in tents.

Musical for Hospital.—A musicale was held Monday evening, February 5, for the benefit of the Williamsburg Hospital, in Brooklyn. This hospital has been open to the sick poor for the past sixteen years and this is the first appeal to the public for money, though the demands on the hospital have been very great, and of late many needed improvements have been made at great expense.

Contagious Diseases.—There were reported to the sanitary bureau for the week ending January 27, 1,468 cases of measles, with 34 deaths; 404 cases of tuberculosis, with 178 deaths; 348 cases of diphtheria and croup, with 41 deaths; 226 cases of scarlet fever, with 16 deaths; 29 cases of typhoid fever, with 5 deaths; 23 cases of cerebrospinal meningitis, with 16 deaths, and 215 cases of variella; a total of 2,713 cases and 290 deaths.

Public Hospitals Commission.—Mayor McClellan has appointed a commission to reorganize the administrative methods of the public hospital system of this city. The city is about to expend a large sum of money for the extension of the public hospital system and it is the mayor's idea that the whole system should be brought under one controlling body. The commissioners of charity, health and tenement house departments and the president of Bellevue and the allied hospitals are among the members of this commission. In a letter to the new commissioners the mayor has asked them to consider the problems presented by existing methods of administration and to propose such remedies as may be necessary to correct the defects of the present system. They are asked to inquire after the future needs of the city in regard to caring for the sick poor so that adequate provision may be made for carrying on this work. A report is requested so that if necessary legislation may be secured to give the city a better system than that under which it now works.

NORTH CAROLINA.

General Hospital for Raleigh.—A movement is on foot in Raleigh, headed by Dr. Hubert A. Royster and backed by the board of trade and leading citizens, to secure a large general hospital for the city.

Tri-State Society.—The eighth annual session of the Tri-State Medical Association of Virginia, North Carolina and South Carolina will be held at White Stone Lithia Springs, S. C., February 27 and 28.

Society Elections.—The Iredell-Alexander County Society has elected officers for 1906 as follows: President, Dr. E. E. Kluttz, Troutmans, and secretary, Dr. John E. McLaughlin, Statesville.—The Haywood County Medical Society has elected the following officers: President, Dr. J. Rufus McCracken, and secretary, Dr. J. Howell Way, both of Waynesville, N. C.

New Superintendent.—At the meeting of the trustees of the State Hospital for Colored Insane, Goldsboro, January 24, Dr. William W. Faison, for some years first assistant physician, was elected superintendent in place of Dr. John F. Miller, deceased. Dr. Faison is well qualified and has rendered the hospital excellent service for several years past. His election was unanimous, Drs. Cobb and Jordan, the other leading candidates, withdrew in his favor before the election was held.

OKLAHOMA.

Physicians as Mayors.—Three or four of the largest towns of Oklahoma and Indian Territory have elected physicians in active practice as mayors during the past year.

Personal.—Dr. Ulhus L. Russell, Oklahoma City, returned from London, December 29.—Dr. H. Coulter Todd, Oklahoma City, who is now at Moorfield's, London, returned February 1.

Hospital News.—The Mangum Hospital was destroyed by fire November 22.—The crowded condition of St. Anthony's Hospital, Oklahoma City, has been relieved by the recent opening of the large addition to the old building.

PENNSYLVANIA.

Personal.—Dr. Warren F. Klein, Lebanon, has been appointed a member of the local board of medical examiners by the commissioner of pensions, vice Dr. Charles L. Miller, resigned.

Philadelphia.

Statue of Dr. Leidy.—On February 1 council's committee on city property acted favorably on an ordinance granting permission for the erection of a statue to Dr. Joseph Leidy on the City Hall plaza.

Medical Alumni Meeting.—The medical alumni of the University of Pennsylvania will give their annual banquet February 21. Dr. Wharton Sinkler, representing the board of trustees as well as the medical alumni, will preside, and Dr. George E. de Schweinitz will be toastmaster.

Malpractitioner Sentenced.—"Dr." Mary Roberts, charged with performing a criminal operation, was sentenced by Judge von Moschizker, January 30, to three years' imprisonment. Mrs. Roberts is the wife of William Roberts, who was sentenced to seven years' imprisonment in Boston for complicity in the murder of Susan Geary, the victim of the dress-suit case tragedy.

Hospital Reports.—During January 63 patients were under treatment at the Kensington Hospital for Women. There were 27 patients in the hospital January 1, and 29 are still under treatment.—The Germantown Hospital admitted 132 patients in January and discharged 92, the number remaining on February 1 being 85. During the month 1,700 cases were treated in the dispensary.

Bequests.—By the will of the late Nannie M. Fidler the Philadelphia Home for Incurables will receive \$5,000 for the establishment of a free bed in the women's cancer ward; the will also devises \$10,000 to Dr. Charles S. Mills.—The will of the late Nicholas Lanning contains bequests of \$10,000 for the Maternity Hospital, \$5,000 for the Philadelphia Dispensary, and \$5,000 for the Sanitarium Association.

Personal.—Dr. William W. Keen was a guest of honor at the annual banquet of the Bucknell Alumni of Philadelphia, at the University Club, February 1.—Dr. Theodore H. Weisenburg has been appointed secretary of the Section on Nervous and Mental Diseases of the American Medical Association for the ensuing year, to take the place of Dr. David I. Wolfstein, Cincinnati, who is ill.—Dr. Edward H. Nichols, Boston, gave an illustrated address to the Philadelphia Pathological Society, February 8, on "The Pathology of Chronic Non-tubercular Arthritis."—Dr. and Mrs. Oliver P. Rex sailed from New York for a cruise to the Mediterranean and the Orient, January 30.—Dr. and Mrs. Alexander Williams Biddle will leave for Japan next month.

Health Report.—The total number of deaths from all causes reported during the week aggregated 751, a decrease of 12 from the number reported last week, and an increase of 33 from the number reported in the corresponding week of last year. The principal causes of death were: Typhoid fever, 21; measles, 26; whooping cough, 7; diphtheria, 13; tuberculosis, 55; cancer, 21; apoplexy, 20; epilepsy, 4; heart disease, 51; acute respiratory disease, 127; enteritis, 29; Bright's disease, 40; old age, 7; suicide, 3; accidents, 17, and marasmus, 4. There were 509 cases of contagious disease reported, with 34 deaths, as compared with 476 cases and 31 deaths. There was a slight increase of typhoid fever during the week, 344 cases, with 21 deaths, being reported, as compared with 339 cases and 17 deaths in the preceding week.

Efforts for Sanitary Trolley Cars.—Dr. Coplin, director of public health and charities, has instituted general inspection of the street-car service of the city for the purpose of framing regulations to protect public health against dirty, overcrowded and poorly ventilated cars. In a letter submitted to the chief of the health department he requests a careful examination of all trolley cars, and the report to be submitted to the department containing such information as may come within their personal observation, particularly on the following points: General cleanliness.—In case any car is in a condition believed to be prejudicial to public health the officer shall transmit to the chief medical inspector the license and running number of the car, the line, the date and hour when the observation was made, and the points between which the reporting officer was a passenger; and the officer shall state in

detail the condition believed by him to be detrimental to public health. Spitting.—In case any officer of the bureau of health observes evidence of spitting in public cars he shall report the conditions under which the observation was made, as indicated above; whether the conductor could have easily determined the fact that this violation had occurred, and whether the conductor made an effort to suppress the nuisance. All noisy, rattling cars are also to be reported.

WISCONSIN.

New Hospital for Appleton.—Dr. Albert M. Freund is erecting a private hospital on Superior Street, which will probably be ready for patients in the spring.

Proposed Tuberculosis Sanitaria.—A movement is reported to be on foot to establish a sanitarium in Milwaukee for the treatment of tuberculosis. A similar movement is contemplated in La Crosse.

New Home for Epileptics in Milwaukee.—The Riverside Sanitarium property on Humboldt Avenue is to be used by members of the various Lutheran congregations as a home for epileptics and feeble-minded individuals.

GENERAL.

Fraudulent Solicitor Arrested.—H. Fred Mace, a fraudulent solicitor of magazine subscriptions and of subscriptions to *THE JOURNAL*, regarding whom a warning was issued in *THE JOURNAL*, January 27, has been arrested in Los Angeles. Any physicians who have been victimized by this individual are requested to communicate with Mr. James Horsburg, Jr., assistant general passenger agent, Southern Pacific Railway, 431 California Street, San Francisco.

Rockefeller Institute Scholarships.—The Rockefeller Institute for Medical Research offers for 1906-07 scholarships to assist investigations in experimental pathology, bacteriology, medical zoology, physiology and pharmacology, and physiologic and pathologic chemistry, to be carried on in the laboratories of the institute in New York City. The value of these scholarships ranges from \$600 to \$1,000. They are open to men and women who are properly qualified to undertake research work in any of these subjects and who will devote their entire time to it. Applications and credentials should be in the hands of the secretary of the Rockefeller Institute, Dr. L. Emmet Holt, 14 West Fifty-fifth Street, New York City, not later than April 1, 1906. The announcement of the appointments is made about May 15. The term of service begins preferably on October 1, but, by special arrangement, may be begun at another time.

Report of the Recent Yellow Fever Epidemic in Cuba.—The local board of health of Havana has issued a report of the recent yellow fever epidemic in Cuba. The report states that the most likely source of infection was undoubtedly New Orleans, where the disease had prevailed since July. Once a week a steamer made direct trips between New Orleans and Havana, covering the distance in less than three days, with the aggravating circumstance that it was never fumigated at either port, and that during its stay at New Orleans it was tied to a wharf situated in one of the most severely infected quarters of that city. In Havana the measures taken against these steamers consisted in forbidding their approach to the wharves and only allowing cargo to be taken from or into the vessel in lighters by means of immune persons. All persons not immune were held in strict quarantine for five days. Immune passengers, on the other hand, were allowed to land without restrictions of any kind. While the disease is practically wiped out, the report goes on to state that it would be a grave error to think that all preventive measures may be omitted, as sporadic cases may still be expected to occur; some of them so mild that the diagnosis might be difficult or even impossible on purely clinical data. Attention is called to the necessity for continued vigilance and for the destruction, so far as possible, of all mosquitoes and their breeding places.

Health Report of the Philippines for September.—The report of the Board of Health for the Philippine Islands for September states that during the month 692 births were registered and 1,068 deaths. Of the births 368 were males and 324 females. The most prevalent causes of death were, in the order of their frequency: Convulsions (under 5 years), 245; tuberculosis of the lungs, 128; Asiatic cholera, 126; diarrhea and enteritis (2 years and over), 72; meningitis, 58; acute bronchitis, 56; beriberi, 38; dysentery, 36; congenital debility, 19; etc., 31; chronic diarrhea and enteritis (under 2 years), 29; chronic bronchitis, 25; senile debility, 20; diarrhea and enteritis (under 2 years), 17; tetanus, 14; organic disease of the heart, 13; malarial fever, 12; chronic rheumatism and

gout, 8; bronchopneumonia, 8; acute nephritis, 8; chronic nephritis, 7; congestion and hemorrhage of the brain, 7; intestinal parasites, 6; typhoid fever, 5; tuberculosis of the meninges, 5; angina pectoris, 5; leprosy, 4; pneumonia, 4; puerperal hemorrhage, 4; accidental traumatism, 4; accidental electrocution, 4; malarial cachexia, 3; purulent infection and septicemia, 3; tuberculosis of the abdomen, 3; cancer and other malignant tumors of other organs not specified, 3; anemia, chlorosis, 3; acute endocarditis, 3; pulmonary congestion, 3. There was one case of smallpox, with no deaths registered during the month. There were two cases of bubonic plague, with two deaths.

FOREIGN.

Accidents in British Coal Mines.—Though there were 62 fewer separate fatal accidents in the coal mines of Great Britain and Ireland in 1905 than in the previous year, the deaths increased by 95, the figures being 1,150 as compared with 1,055 in 1904.

Exhibition of History of Medicine in Art and Crafts.—Dr. Holländer of Berlin (No. 3 Kleiststrasse), is in charge of the historical exhibit which is to be one of the features of the festival inauguration of the Empress Friedrich House at Berlin, the center for postgraduate instruction. The exhibit is to be opened this month and continue to the middle of April.

Rinecker Prize Goes to Overton.—The triennial Rinecker prize given by the medical faculty of Würzburg, Germany, was awarded this year to E. Overton, assistant at the Würzburg Institute of Physiology. His researches on the osmotic properties of cells, the mechanism of narcosis and the importance of the mineral elements for the functions of the cells have attracted much attention among physiologists.

The Queen of Portugal and the International Medical Congress.—Queen Amelie of Portugal is interested in nursing and in medicine and took a course of instruction in these subjects a few years ago. The Lisbon faculty of medicine conferred an honorary degree of medicine on her in token of appreciation of her interest in science. It is now stated that she has been appointed honorary president of the approaching International Medical Congress, which opens at Lisbon, April 19.

Official Medical Fees in Case of Industrial Accidents.—*THE JOURNAL* in its issue for January 13, page 141, gave the text of the recent French decree regulating the medical fees in case of industrial accidents. It went into effect last November. Previous to that date the remuneration of the physician attending a workman injured while at work was the same as that paid by the authorities for medical care of the indigent. The *Semaine Médicale* took the lead in calling the attention of the authorities to the injustice of this remuneration. The workman is not a pauper, and the employer should pay for his treatment accordingly. The result was the promulgation of the decree referred to which was first published in full in the *Semaine Médicale* for October 11.

The Physicians of Germany.—Heinmann compares the statistics for 1905 with those of other years in regard to the number and distribution of physicians in Germany, his article appearing in the last number of the *Deutsche med. Wochts.* for 1905. The total number in the empire is 31,041. Greater Berlin has 3,970; Berlin proper has two less than last year. More than one-eighth of all the German and one-fifth of all the Prussian physicians live in Berlin. In 1905 throughout the empire only 1,057 medical graduates received the state "approbation" which entitles them to practice as regularly qualified physicians, and in Prussia only 362. The corresponding numbers in 1900 were respectively 1,384 and 662. The number of medical students enrolled has dropped from 8,986 in 1890 to 6,288 in 1905.

Records of Details in Regard to Operations.—A letter from Vienna in the *Münch. med. Wochts.* states that the minister of the interior has recently decreed that in all private hospitals and clinics the names of the operator and of the assistants, both medical and lay, must be recorded for each operation. It is possible that the measure may be extended to include the public hospitals. The motive for the decree was a suit brought on account of the death of a woman who had been operated on a few weeks before in a Vienna hospital. A sponge was found in her abdomen, left from the operation, and a suit for damages was instituted. The suit had to be dismissed, as the authorities were unable to discover who was the responsible party, there being no record of the person in charge of the instruments and sponges at the operation.

Tuberculosis and Workmen's Insurance in Germany.—Their statistics for the German empire during the years 1900-1904 have just been published by the societies for compulsory

insurance of workmen against sickness. They show the money received and paid out for sanatoria, hospitals, building loans, etc., the number of sick treated and the results of treatment, both immediate and remote. In a communication in the *Deutsche med. Wochs.*, No. 52, Wagner comments on the figures presented, remarking that they show again the terrible extent to which the working classes are decimated by tuberculosis. The results of treatment are constantly growing better, however, and the only hope, he thinks, is in the extension of the sanatorium movement. He notes that the cures realized in tuberculous women are more apt to be permanent than in men.

German Society for Total Abstinence Among Physicians.—This long established society has now decided to issue reports addressed to the medical press to keep the medical journals informed in regard to matters affecting the liquor question from the medical point of view, and also in regard to the movement for total abstinence among physicians at home and abroad. The reports are to appear as material accumulates, and are sent out as a "Korrespondenz-Blatt," edited by Dr. Arnold Hultsch of Pöthenhammer. The first number contains a warning against a new German periodical *Das Leben*, which was founded by the brewery interests but masquerades as a scientific journal. It was able to secure articles from Ewald, Goldscheider, Litten and other prominent scientists for its first numbers. Their articles were altered in such a way as to make them an endorsement of alcohol, in some instances absolutely contradicting the authors' well-known views.

Child Mortality in London.—The report of the medical officer of the London County Council has just been made public, and in regard to the mortality among infants and young children provides some instructive reading. It is a matter of more or less common knowledge that about 20 per cent. of children born in most cities are doomed to death owing to the conditions under which they are born. This, however, has been generally regarded as to a large extent, a terminating evil. According to the report issued recently, "the adverse environment which slaughters one in five of the infants born has a maiming effect on those left." There has been a tendency to look on a high death rate of infants as a natural weeding out of the unfit, leaving the strong ones to survive in order to propagate a hardy race. This view can no longer be held, as experience has shown that many of the survivors are liable to develop into weaklings, and frequently to become progenitors of useless children.

International Laryngo-Rhinological Congress as Memorial to Türk and Czermak.—The Vienna Laryngological Society ("Wiener laryngologische Gesellschaft") is sending out an appeal to all interested in laryngology and rhinology to unite in a worthy memorial to Türk and Czermak on the fiftieth anniversary of their pioneer work in clinical laryngology and rhinology. It is proposed to have the jubilee celebration take the form of an international congress for these specialties, to be held at Vienna, April 21 to 25, 1908. The appeal is signed by the president of the society, Prof. O. Chlari, I. Bellariastrasse 12, Vienna, Austria, and the secretary, Prof. M. Grossman, IX, Garnisonsgasse 10. They request that each scientific society, especially those devoted to these specialties, will appoint some one of its members who will remain in constant correspondence with the president of the acting committee in reference to all matters concerning the congress. The invitation to laryngologists and rhinologists to take part in the congress is cordial and urgent. The favor of an early acceptance is requested.

From Russia.—Notwithstanding the strikes and uprisings in Russia, our medical exchanges have been regularly received, without any interruption to date, even in the receipt of the *Meditsinskoe Obozreniye*, which is published in Moscow. They pursue the even tenor of their scientific way, apparently undisturbed, although they refer incidentally to the "prevailing unrest," and contain occasional obituary notices of medical men and women arrested or killed on account of their revolutionary activity or by the rioters. The privat docent for pathologic anatomy at Moscow, V. Worobioff, was shot by soldiers recently. They were searching his house, where he had established an emergency shelter and hospital for persons injured in the revolutionary movement. He was vice-president of the Moscow Therapeutic Association last year. The Russian Surgical Congress and the National Medical Congress were to have convened at Moscow early in 1906, but on account of the disturbances there both have been postponed *sine die*. The medical officials connected with the district hospitals are assumed by the indignant populace to be partisans of the autocracy, and they have had to flee from the

rioters. In many places the hospitals have been destroyed, and at Tver nine physicians were seriously injured. The Czar has recently conferred various decorations on a large number of physicians for courage and devotion during the campaign in Manchuria.

Consumption and Marriage.—The question as to whether or not consumptives should marry has been widely discussed in America of late years, at frequent intervals. In Great Britain the matter has not received much attention. It would seem now as if the subject possesses interest for the general public, for one of the principal lay journals of a recent date contains an article on consumption and marriage written by a well-known medical man. The writer points out that immunity or susceptibility to pulmonary tuberculosis are determined, to an exceptional degree, by the bodily health. That is why consumption is in general a disease of the lower classes in Great Britain, the fewer victims of the upper classes paying the penalty for the indifference of their class to the misery beneath them. In short, a person who comes into this world with a family history of consumption stands a better chance of being a healthy individual, provided that a sane and out-of-door life is led, than the person who has a clean bill of health, so far as ancestors are concerned, but who either from compulsion or choice, lowers the vitality of the system by breathing foul air and living amid general insanitary surroundings. As to marriage of individuals having a consumptive family history, the writer is like the late premier of England on political questions, somewhat noncommittal. He states that, professed advocate of eugenics though he be, the marriage of persons having a consumptive family history can not be altogether condemned. He declares in almost the same breath that "if some of us are to marry and some are not, I would rather in a general way, that those who have a bad family history remain in single blessedness." Perhaps, after all, this is the most sensible mode of regarding the matter, although, of course, it stands to reason that those who have acquired the disease would far better not marry.

Makes Artificial Albumin.—Our German exchanges announce that Emil Fischer has succeeded in the synthetic production of certain bodies resembling peptones. His communication was presented at a meeting of the German Chemical Society at Berlin, January 6, and the mere preliminary announcement of his address attracted a crowd of eminent scientists from all over Europe. Fischer is professor of chemistry at Berlin and has an international reputation as the "master of synthetic chemistry." In his latest research he sought to produce the aluminoses and peptones by reversing the process of their production, commencing by blending together certain amino acids, the resulting compounds possessing properties which correspond to those of the peptones. They present all the more important reactions of the peptones, and he calls them *peptids*. He can make them with 2, 3, 4, 5, 6 and 7 different amino acids, and has thus succeeded in producing 80 different kinds of peptids. He distinguishes them by the number of molecules, the same as the saccharids, calling them dipeptids, tetrapeptids and so on to polypeptids. The peptids are optically active like the natural proteins, and the more complicated the peptid the more closely it resembles natural derived albumin. The polypeptids give the biuret reaction, they are precipitated by phosphotungstic acid, and the trypsin of the pancreatic juice splits a number of the artificial peptids, with the same resulting products as in hydrolysis of the proteins. To complete the researches it was only necessary to succeed in producing a peptid from natural derived albumin, to fit the last link into the chain of the synthesis of albumin. This he has accomplished with silk fibrin, a comparatively simple derived albumin, which he was able to reduce to glycyl-alanin, identical in every respect with the artificial peptid glycyl-alanin.

The Danger of Ice. Sir Shirley Murphy, medical officer of health to the London County Council, has recently called attention to the danger of allowing natural ice to come into contact with beverages and foodstuffs. He refers to the matter in part as follows: "As regards the conditions under which the ice industry is carried on, there are undoubtedly certain sources of risk of contamination incidental to the manipulation of ice in London, but the main question to be decided is the advisability of employing natural ice under circumstances in which it comes into actual contact with beverages and with food. Having in view the facilities which may exist for obtaining artificial ice, it appears not unreasonable to suggest that for all purposes in which there is actual contact with food, ice made from absolutely pure, and preferably from distilled water, should be used, inasmuch as the source

of natural ice can never be known with certainty by the consumer." Dr. Hamer, assistant medical officer to the council, points out that it is necessary to call attention to the need of supervision of cold stores. The New York legislature last year had under consideration a bill for the inspection of storage warehouses located in cities of the first class; to insure sanitary conditions in these stores, and to give the inspectors authority to condemn any foods stored therein which are considered as unfit for use or deleterious to health; also to provide a license fee of \$500 per annum for such inspection. Dr. Hamer also called attention to the fact that the attempt has been made in Chicago to provide for the inspection of cold-storage plants and to limit the time of storage of perishable goods. In the salmon and fresh water fisheries bill, introduced into the British house of commons last year, it was proposed to make compulsory the registration of refrigerating premises in which salmon may be stored. Finally, it was pointed out that it will probably be found necessary in the near future to require registration of all cold-storage plants, as the possibilities of mischief in the case of a cold store are greater than they are in that of a dairy, yet the latter is subject to control by the health authorities, while the former is not.

Free Sanitarium Treatment of Non-tuberculous Affections Among the Working Classes of Germany.—Much has been written about the sanitarium treatment of the tuberculous policy holders in the insurance against sickness now compulsory in Germany, but little has been said in regard to courses of treatment given to non-tuberculous affections. It seems, however, that during the last seven years 67,795 men and 41,765 women have been given a free course of treatment on account of rheumatism, gout, heart and lung affections, anemia, urinary or venereal affections or imbecility. The average length of the course of treatment was about fifty days. The treatment of these affections is less expensive for the insurance companies (Krankenkassen) than that of tuberculosis, as the courses are shorter and forced feeding is not required, the total cost for each patient averaging about \$50 for the former and \$90 for the latter. The number of venereal cases admitted to treatment was 473 in 1904, 508 in 1903, 333 in 1902, and 142 in 1901. The insurance companies have not found it necessary to establish special institutions for the care of their non-tuberculous sick policy enscri holders, but distribute them as pay patients in existing hospitals, clinics, convalescent homes, etc. Out of each 100 thus treated, from 34 to 38 are still gaining their own livelihood after an interval of five years. The permanent results are thus from 4 to 7 per cent, more favorable than with the tuberculous beneficiaries. In a communication to the *Deutsche med. Wochts*, for January 4, Wagner analyzes and comments on the statistics recently published by the insurance societies. He remarks in conclusion that during the last seven years 88,000 tuberculous working people have been treated in special sanatoria, over 59,000 other sick persons in various hospitals, and over 36,000 others at the best watering places of Europe. In nearly every instance the course of treatment was a long one, causing considerable expense. Under other conditions these prolonged courses of treatment are possible only for the well-to-do. The classes of society which hitherto have had to do without calling in a physician to attend them in case of illness are now treated by eminent specialists and receive prolonged care in a suitable medical institution. The results on the whole are very encouraging, but at first not quite so favorable in the non-tuberculous as in the tuberculous cases, although the latter outcome is better.

Sanitary Measures in French African Possessions. Small-pox is very prevalent in the Senegal country, southwest of the Sahara desert, and efforts have been made to introduce vaccination without success. The lack of calves for obtaining the vaccine and the fact that vaccine material brought from Europe spoils on the long trip, render it impossible to apply the usual methods of vaccination. Arm to arm vaccination was tried but proved expensive, and is liable to be dangerous, as syphilis and leprosy are so frequently encountered. Consequently this method had to be abandoned. Promising experiments are now under way in which rabbits and gazelles are used for the vaccine producers. An epidemic of yellow fever decimated the population of Senegal in 1900, but within the last year or so an effective system of "mosquito brigades" has been established among the natives, which have done remarkably fine work. Armed with shovels and pickaxes, cement and limesone, they visit every nook and corner of the towns, villages and stations. An account in the *Semaine Méd.* for January 10 states that the natives have taken hold of this work with zest and have co-operated in promptly isolating the occasional cases of yellow fever encountered, so that no con-

tagion has resulted in any instance from the imported disease. Similar prophylactic measures have been undertaken against malaria, screening of houses, etc., and the reduction in the number of cases among the employés of the railroads and the soldiers has been strikingly apparent. At some places the results were nullified by tacking the netting to the window blinds. This prevented the opening of the blinds for ventilation so that the men preferred to sleep on the verandas. Numerous regulations in regard to hygiene have been enforced and boards of public health appointed in various communities. The authorities pay about \$2,400 a year to certain civilian physicians who reside in populous native centers to instruct the natives in hygiene and give them medical attendance. They are engaged for five years with six months leave of absence twice after two years of service. Circulars and pamphlets giving the prophylactic measures against various diseases of man and animals have been distributed freely, and the *Journal Officiel*, published by the governor general of French Western Africa, devotes much space to suggestions in regard to the care of the health in general, and under the local conditions.

LONDON LETTER.

Fracture Dislocation of the Shoulder; Action Against a Doctor for Malpractice.

At the Glamorganshire assizes a mining engineer brought an action for negligence against Dr. Skyrme and Mr. Lynn Thomas (the leading surgeon in South Wales), in which occurred a most regrettable conflict in the evidence of eminent surgeons. The plaintiff was knocked off a bicycle, receiving a violent blow over the right shoulder, with lacerations of the face, wrist, hand, knee and ankle on the right side. Half an hour later he was seen by Dr. Skyrme, who discovered a dislocation downward of the head of the humerus, with swelling of the shoulder. By pulling on the limb with his foot in the axilla he was able to reduce the dislocation, but finding crepitus and effusion in the axilla, he anticipated serious complication and expressed a wish for a second opinion. Mr. Lynn Thomas saw the case and confirmed Dr. Skyrme's serious prognosis. There was one-half inch shortening, showing that the fragments were overriding; the pulse was small compared with the opposite side, and the veins of the forearm were engorged. It was thought advisable to submit the limb to the manipulations necessary to bring the fragments into end-to-end apposition. As it was thought dangerous to apply the usual methods for retaining the fragments in position, lateral apposition was obtained by bringing the elbow to the side and fixing it there. The usual large pad in the axilla was omitted, only a small pad being used. During the following night the plaintiff removed the small pad from the axilla. Some days later Dr. Skyrme found him lying in bed with an ambulance book in front of him and a set of bandages, which, with the assistance of the nurse, he was endeavoring to arrange. Subsequently a skiagraph was taken and shown and explained to the patient. His case was largely based on this and other skiagraphs taken subsequently. They showed displacement inward of the upper end of the lower fragment, in which position union took place. The plaintiff stated that the arm was crippled, though he admitted that he could use the hand. In order to obtain evidence in support of his case he visited various medical men, but met with difficulties in inducing them to give evidence. At the action, Mr. A. J. Pepper, Mr. W. Rose and Mr. W. H. Battle gave evidence on his behalf. Mr. Pepper did not accept the evidence given by Dr. Skyrme and Mr. Lynn Thomas as to the nature of the injury. His opinion was that there had been no dislocation and no such interference with the circulation as to threaten gangrene. He thought that the deformity ought to have been reduced at the time of the accident and that failing, that the open operation should have been advised when the skiagraph showed the extent of the displacement. Mr. Rose and Mr. Battle agreed with this evidence and expressed the opinion that the treatment was improper. Mr. Lynn Thomas stated that he informed the patient that the result of a skiagraph could not affect the treatment, emphasized the need of keeping a strict lookout for further embarrassment of the circulation, and dismissed the idea of open operation. For the defendants, Sir Thomas Smith stated that the only proper judges as to what should have been done on the day of the accident were the physicians in attendance, and that he did not think that operation at a later stage, with a view to replacing the fragments, would have improved matters, his experience being that such an operation usually left the patient worse. When asked whether the x-rays had modified treatment he said, "They have largely increased actions at law." Mr. Mansell Mouillon

and Mr. Robert Jones also gave evidence on the same side, the former stating that an attempt to bring the fragments into apposition on the day of the accident would have been dangerous, considering the injury to the vessels, nor would he have favored operation at a later stage. The jury disagreed and was discharged.

Sanitation in West Africa and in India.

Lieut.-Col. Giles has published a valuable report on an expedition sent by the Liverpool School of Tropical Medicine to investigate general sanitation and antimalarial measures in Sekondi, the West African gold fields, and Kumassi. He also makes a comparison between the conditions of European residence in the Gold Coast and those existing in India. At Sekondi, the point of commencement of the railway which now extends to Kumassi and which is intended to open up the Hinterland, a rapid growth of population, both European and native, is practically certain. The report dwells on the importance of maintaining a complete separation between European and native dwellings, even when the latter are occupied by native clerks, who are "people of education and quite inoffensive neighbors from a social point of view," the fact remaining that they and their families are as dangerous sources of the malarial parasite as their less cultivated countrymen. The daily association with natives for business purposes appears to be unobjectionable, but their blood is liable to supply the malarial parasite to mosquitoes, who may then convey it to Europeans sleeping in the vicinity. In addition to the separation of residential quarters it is declared necessary to fill up two lagoons which intersect the town and furnish extensive breeding places for mosquitoes. The railway to Kumassi calls for observation only on the score that its rolling stock is ill-adapted to the requirements of tropical traveling. Kumassi itself is infected by mosquitoes and also by a fly analogous to the tsetse and like it a carrier of trypanosome fatal to horses, and its site is declared to be so unfavorable to antimalarial operations that the best solution of the difficulty would be to remove the seat of the district government to some more favorable position. Failing this, it is probable that a great improvement of the existing conditions might be brought about by a thorough draining of the surrounding marsh. A favorable report is given, not only of the possibilities of antimalarial sanitation in the mining districts, but also of what has been accomplished. Stress is laid on the economy attendant on these measures. The financial success of a mining company depends far more on them than is usually recognized. The cost of paying and nursing sick men and the heavy expenses involved in invaliding and replacing them are a heavy drag on the industry which might be lessened by steady attention to sanitation, which would yield handsome interest on the money expended. As a general result of a comparison between the salubrity of West Africa and that of India, Colonel Giles concludes that there is not much difference between the two climates and that the main reason for the better health of the Anglo-Indian is that he has made himself more comfortable in his surroundings and that the unsanitary habits of Indian natives has led to the European living quite apart from the native and with consequent lessened liability to the contraction of native diseases.

Sanitary Measures in India in 1903-4.

The annual blue-book just issued on this subject contains much valuable information. The general health was less satisfactory than in 1902, chiefly owing to epidemics of cholera and plague. The mean death rate for India was 34.7 per 1,000 as against 31.5 in 1902. The mortality in the Bombay presidency was 43.9, the highest on record, with the exception of the terrible famine year of 1900. Plague alone claimed 92,000 victims in Belgian and Dharwar, thus raising the mortality of these districts to 70. The mortality of the chief diseases was as follows: Fevers, 19.6; plague, 3.03; cholera, 1.37; dysentery and diarrhoea, 1.21; smallpox, 0.41. In the European and native armies, on the other hand, the mortality was abnormally low, one of the main reasons for which was their comparative immunity from plague. As usual, the chief causes of sickness among British troops were malarial and venereal disease, which accounted for 23.9 and 23.5 per cent., respectively, of all admissions to hospitals; but these diseases were not very fatal and the chief cause of mortality was typhoid fever which was responsible for 32 per cent. of deaths from all causes in the European army, while hepatic abscess was the cause of 10 per cent. British rule has conferred no greater boon than the hospitals and dispensaries, of which there were 2,500 in 1903. No fewer than 372,857 in-door and 22,399,350 out-door patients were treated. The number of

operations constantly increases, especially those for cataract. Out of 854,000 operations only about 2,000 proved fatal.

Extraordinary Attempt to Obtain Compensation by Self-Inflicted Mutilation.

An extraordinary attempt to obtain compensation by self-inflicted mutilation has been the subject of an action in the courts. At the first trial, the jury disagreed, but at the second they found a verdict against the plaintiff. According to his story, he was traveling alone in a compartment on the Tall Vale Railway (in Wales). He stood up soon after leaving the station in order to place his umbrella on the rack opposite, and in doing so was caused to reel against the door by a sudden jerk of the train. The door was open, owing to the negligence of the company's servants, and he fell out, with the result that he lay with his feet across the other line of rails, insensible, and a train passed over his legs, so crushing them as to necessitate double amputation. This tale not only lacked corroboration, except in the matter of injuries, but was contradicted by evidence for the company. The company's servants swore that, when the train left the station, there was no traveler in the compartment which he described, and no door was found open at the next station. The locomotive superintendent found by experiment that no jerk took place when the train passed the place of the alleged fall. On the other hand, it was possible for the man to have got there by walking along the line in the dark, and he could have bought the railway ticket found on him before starting. In addition to the motive to obtain compensation from the railway company, he had in his possession no fewer than three coupon-bearing newspapers which insure their purchasers against railway accidents. Another fact which told against him with the jury was that, before the alleged accident, he spoke to his acquaintances of a dream which foretold the loss of two legs below the knee. But the medical evidence told still more strongly against him. His injuries were confined to the crushing of both legs in a straight line, and it was difficult to explain how he could have fallen and remained in the attitude necessary for this to occur, or how the accident rendered him unconscious and left no physical traces, not even bruises. Moreover, after the train passed over his legs, he showed no sign of the dazed condition usually associated with a severe fall and insensibility. He summoned a miner who was passing and gave him detailed directions for the improvisation of tourniquets for both thighs, and the physician who was called was struck with his coolness. On being moved into a van, he put out his hands to guide the passage of the shutter on which he lay. When told his legs must be amputated, he replied: "Yes, I will have my two legs off below the knee." The jury rejected his claim. This case is one of the most remarkable instances on record of the extent to which a man will inflict injury on himself for the purpose of obtaining compensation.

The Battle of the Nurses.

A serious difficulty has arisen among the nurses. In Great Britain there are no fewer than 80,000 nurses. Many thousands of these have spent much time and money in reaching a high standard of efficiency; but in engaging a nurse the public have no guarantee that she knows her business. Any girl can put on a cap and apron and call herself a trained nurse. The term "certified nurse" counts for something with the public, but it guarantees very little. There is no control over the hospitals in the issue of certificates. In some hospitals a girl can obtain a certificate after only six months of the most elementary work. In others she has to serve four years and to pass a difficult examination. A demand is now being made by these highly trained nurses for registration by the state and an established standard by which efficiency may be recognized. The agitation for registration began in 1887 with the foundation of the Royal British Nurses' Association by Mrs. Bedford Fenwick, who was for many years a nurse and matron in a large hospital. Subsequently a split occurred on the question of registration. A part of the association, headed by Mrs. Fenwick, seceded and formed the "Society for the State Registration of Nurses," which is now in a flourishing condition. Both societies drafted parliamentary bills which were duly blocked, but in 1904 a select committee of the house of commons considered the question and recommended the registration of nurses by a board to consist of twenty-one members. A battle is now being waged between the two societies. The older society asks that the nurses should be represented on the board in the proportion of one to five physicians, while the younger society claims that there should be a preponderance of physicians.

Pharmacology

No Longer Members of the Proprietary Association.

The Lambert Pharmaceutical Company, St. Louis, ask us to announce that they have withdrawn from membership in the Proprietary Association of America.

Formula of Ayer's Cherry Pectoral.

Dr. Frank L. Smith, Stafford Springs, Conn., writes as follows: "In a recent number of THE JOURNAL you printed a copy of the formula of 'Ayer's Cherry Pectoral.' In the issue of January 6, Dr. Henry Leffman of Philadelphia also presents one in which he notes the fact, which struck me most forcibly, that the above nostrum was sold years, probably thirty or forty, before the introduction of terpin hydrate or heroin. Something like a year ago I saw in a medical journal an offer of the Ayer people to send samples and formula of their pectoral to any physician requesting it. Out of curiosity I wrote asking for it, and here is an exact copy of the formula sent me:

R. Morphine acet.	10 grs.	1097
Sanguinaria tr.	5 grs.	739
Antimony vin.	5 grs.	
Opium vin.	5 grs.	1160
Pran. virg. vir.	5 grs.	8872

"Can you inform me which is the correct one, and when the change, if any, was made?"

Endorsement of the Fight Against Nostrums.

At a recent meeting of the Central Oklahoma Medical Society resolutions were adopted commending the work of *Collier's Weekly* and the *Ladies' Home Journal* in exposing "patent medicine" frauds.

Similar resolutions were passed by the Oklahoma County (Okla.) Medical Society and by the Venango County (Pa.) Medical Society. The latter society, in addition, commended the action of the *Evening News*, of Franklin, Pa., in refusing to accept contracts from "patent medicine" firms.

At the last meeting of the Muskegee (I. T.) Medical Society the following motion was unanimously carried:

The Muskegee Medical Society tenders its sincere thanks and appreciation to THE JOURNAL of the American Medical Association for the timely crusade against the nostrums and so-called proprietary medicines and for its stand for an ethical profession.

At a meeting held January 8 the Hemenpin county (Minn.) Medical Society passed resolutions approving the action of the American Medical Association in establishing a Council on Pharmacy and Chemistry and expressing its belief that the work of the council will result in great good, both to the public and to the physician. The society also resolved to support THE JOURNAL of the American Medical Association in its campaign of education in regard to nostrums and medical preparations.

Peruna's Shrewd Advertising.

It is often said that "it is an ill wind that blows no one any good." The successful promoter, whether he be exploiting stocks, the latest book or patent medicine, takes advantage of everything that comes his way to push the sale of his product. Strange as it may seem, the nostrum promoters are taking advantage of the campaign against patent medicines to further the sale of their products. The *New Idea* calls attention to the following advertisement:

"There are people who object to the use of any proprietary medicine on the suspicion that spirits may have been used in its manufacture.

"Even Peruna has not altogether escaped such criticism. But people who have taken Peruna, who have known of the benefits of Peruna by actual experience, know how utterly unfounded such notions are concerning Peruna. When the treasurer of the National Prohibition Voters' League comes out in a public statement to the effect that wood, 'fall to express his praise for Peruna and for the man featured' of Peruna, it must appear to every candid mind how utterly irrational it is to suppose that any objection could be raised on the basis of the shrewdness of the advertiser.

"Peruna, by the way, its friends among the leading temperance workers in this country who give it unstinted praise and do not believe it contains it by the use of the most extravagant language."

The *New Idea* remarks that, since Peruna contains 28 per cent. of alcohol, "this advertisement is distinctly funny in its studied attempt to appeal to temperance people without flatly denying the presence of alcohol. . . . There is undoubtedly much truth in that advertisement. For instance, the first paragraph is true; so also the first sentence of the second paragraph. And we doubt not that every word of the last paragraph could be proved in court; many a temperance worker doubtless finds Peruna very convenient, and after he has had several liberalized doses he would be likely to feel like endorsing it 'by the use of the most extravagant language.' The word 'extravagant' is perhaps used advisedly by the Peruna people; it means, according to the Standard, 'exceeding just or ordinary limits, reason, truth or probability; immoderate; visionary.' Thus it would indicate their own opinion that these temperance workers' praise of Peruna 'exceeds reason, truth and probability.' The enthusiasm of the treasurer of the N. P. V. L. seems directly traceable to the use of Peruna q. s. and is not particularly difficult to account for. We ourselves have seen men in such a condition that they could not think of words to express their praise of something that they had lately been drinking.

"For some reason the Acting Commissioner of Indian Affairs of the U. S. Government does not seem to know that 'it is irrational to suppose that any objection could be raised against Peruna from the standpoint of temperance,' for the horrid thing actually said in his official circular to Indian Agents (August 10): 'The sale of Peruna is hereby prohibited. As a medicine something else can be substituted; as an intoxicant it has been found too tempting and effective.' Commissioner Larabee seems not to know of the benefits of Peruna by actual experience," strongly emphasizing 'benefits.'

"Peruna advertising, in some instances, appears to say more between the lines than on them."

Advertising "Ethical" Proprietaries to the Public.

A Philadelphia correspondent sends us a copy of *The Evening Bulletin* of that city, which contains two specimen advertisements of cut-rate druggists that are suggestive, if not startling. Under the display heading, "Patent Medicines at Cut Rates," in the first of these advertisements, we find 19 proprietary remedies. Of these no less than 12 are advertised in medical journals, are freely prescribed by physicians and are generally claimed to be strictly for physician's use. The second advertisement, while not specifically headed, is more comprehensive, and contains less than 102 titles, of which 13 are soaps or toilet preparations, leaving 89 more specifically medicinal preparations. Forty-two of the latter, or not far from one-half, are so-called "ethical" proprietaries that are widely used by a certain class of physicians. Several of the preparations are dangerous if used indiscriminately, or by those who do not know their action. That this form of advertising constitutes an abuse that can be regulated and controlled by the manufacturer of the preparation is evident. In this connection it may be well to point out to manufacturers who are supplying physicians with "ethical" proprietaries that manufacturers of "patent medicines" have found it practicable to market their wares through regularly appointed retail agents, who are bound by a penalty contract to limit their sales of the several preparations to serially numbered packages, at a specific price. If manufacturers of "patent medicines" can enforce contracts of this kind it would seem that manufacturers of preparations designed for the sole use of physicians could, if they chose, control the sale of their preparations so that they would not be advertised to the public, for whom many of them would be decidedly dangerous.

"Patent Medicines" at the Antipodes.

At the Australasian Medical Congress, held in Adelaide last September, Mr. G. A. Syme, in his address on "State Medicine and Medical Ethics," recalled the circumstances under which the New Zealand parliament passed an act authorizing the framing of regulations making it compulsory that all patent medicines should have the formula printed on the label, and that if any poison were contained in the preparations the bottle must be labeled accordingly. The manufacturers of these preparations and their agents raised such a protest and brought such influence to bear that the regulations were modi-

ried to the extent that the formula instead of being placed on the bottle was to be lodged with the health department. The manufacturers still objected, and as no further alterations could be obtained they decided not to send their preparations to New Zealand. Mr. Syme stated that evidently the vendors of patent medicines clearly realized that once the real nature and commercial value of their preparations became publicly known, there could be no demand for them at their present extravagant prices. In commenting on this the *British Medical Journal* says: "Happy country! which has got rid of this pestilential traffic; but we wonder what our halfpenny press would say if any legislator were bold enough to venture to propose a bill which would deprive them of a large part of their receipts. Some day the public may wake up to the desirability of taking action to check the sale of preparations which are either poisonous or fraudulent, as those which are neither would have nothing to fear from such a law." Evidently the press in Great Britain and her colonies is as much under the dominion of the "patent medicine" man as it is in the United States.

Correspondence

Dr. McCormack's Successful Work.

NASHVILLE, TENN., Feb. 5, 1906.

To the Editor:—I had already learned much of what Dr. J. N. McCormack, as medical organizer of the American Medical Association, has been doing in other states, but was not fully impressed with the importance of his work until I heard him at Gallatin one week ago. This was his first lecture in middle Tennessee, and I was so anxious to learn something of the nature of his work that I visited Gallatin for the purpose of hearing him. He spoke in the courthouse at 2 p. m. to an audience composed of medical men, ministers, lawyers, county officials, business men, teachers and women. Every one present listened intently throughout his talk, which was entertaining, interesting and instructive. I am sure that the members of the county society were made more determined to perform their duties to each other and to the public better than they had ever done before. I am sure that the laity present went home impressed with the fact that physicians are remiss in their duty if they hold themselves aloof from their professional fellows. I was greatly impressed with the importance of having the general public hear Dr. McCormack, for the reason that there are some physicians who need to be driven to the performance of their duties, medically speaking, by public opinion.

If Dr. McCormack were doing nothing else than striking boldly at the patent medicine evil, this alone would justify his being sent out by the American Medical Association. So pleased was I with the lecture, I am now arranging an itinerary for him in middle and east Tennessee which will keep him busy for several weeks. I only wish it were possible for him to visit every county in our state and every county in every other state. I do not believe there is another man in the United States who is as capable as he in the work he is doing.

G. C. SAVAGE.

Poisoning by Kopp's Baby Friend.

OMAHA, Jan. 23, 1906.

To the Editor:—Since reporting to you the case of opium poisoning from the use of "Kopp's Baby Friend" I have seen another child suffering in the same way from the same cause. The medicine in this case had been sent through the mails from the Kopp's at York, Pa.; the bottle bore the additional inducement for use that it was "the king of baby soothers." It seems to be the practice of those people to watch the birth notices published in the newspapers and to furnish free samples of their mixture to the baby's mother, and then our druggist will do the rest. The Antikamnia Chemical Company is using the mails in the same way to bring its goods before the people. I send you herewith a package from that company to one of my patients. It tells the tale. I hope that the proper authorities will put a stop to this infamous use of the United States mail.

ROBERT E. ESKILDSON, M.D.

Association News

NEW MEMBERS.

ELMER S. ALLEN, M.D., Arcola, Ill., to Miss Hannah Rowlands of Judson, Minn., at Chicago, January 23.

GUSTAVUS B. THORNTON, M.D., Memphis, Tenn., to Mrs. Mary Bailey Fowler of Griffin, Ga., January 25.

LOUIS PROVANCE McCOMICK, M.D., of Conellsville, Pa., to Miss Katherine E. Felsing of Northumberland, Pa., February 1.

Deaths

George Ryerson Fowler, M.D., Bellevue Hospital Medical College, New York City, 1871, of Brooklyn, one of the foremost surgeons of New York, died Feb. 6, aged 67, in Albany, N. Y., where he had been in attendance on the centennial meeting of the Medical Society of the State of New York. He died in Albany Hospital from paralytic ileus following an operation for gangrenous appendicitis performed by Dr. Albert Vander Veer, January 20. Dr. Fowler was born in New York, Dec. 25, 1848, the son of Thomas W. and Sarah Jane F. Fowler. He received his preliminary education in the public school of Jamaica, L. I. Soon after his graduation in medicine he devoted his attention to surgery and soon became known as a careful, conservative and skillful operator. He was surgeon to the Methodist Episcopal Hospital, surgeon chief to the Brooklyn Hospital, senior surgeon to the German Hospital, consulting surgeon to St. Mary's, Relief and Norwegian Hospitals. He was professor of surgery at the New York Medical Ex-clinic. He was examining surgeon of the State Medical Examining Board. During the Spanish-American War Dr. Fowler served as chief surgeon of the Third Division, Seventeenth Corps, under General Fitzhugh Lee, and later was consulting surgeon and chief of the operating staff of the Second Army Corps and accompanied General Lee to Havana, where he organized the hospitals. He was discharged from the service Jan. 31, 1899. He was the author of a treatise on appendicitis which passed through two editions and of many other articles on surgical subjects. Dr. Fowler was taken ill on the train on his way to Albany, January 27, and was removed to the hospital January 29, where he was found to be suffering from appendicitis, and an operation was performed which disclosed a gangrenous appendix, which was removed. The paralysis of

the intestine which was found to be present at the time of the operation persisted, however, and caused his death eight days later.

Julian T. Feild, M.D. Tulane University of Louisiana Medical Department, New Orleans, 1861; a member of the Texas State Medical Association, North Texas Medical Association and Grayson County Medical Society; president of the Denton Board of Health; a surgeon in the Confederate service throughout the Civil War; the first city physician of Denison, serving in that capacity for several years; a member of the City Council for five terms; some time president of the Denton Medical Society; a member of the Twenty-fifth Texas Legislature; for thirty years local surgeon for the Houston and Texas Central Railway; and at the time of his death local surgeon for the Frisco System, died at the home of his daughter in Denison, February 1, after an illness of two months, from Bright's disease, aged 64.

William G. Porter, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1868; a member of the American Medical Association; a member of the College of Physicians in 1872 and for many years its recorder; at one time an interne at Blockley Hospital; physician to the Philadelphia Dispensary, and surgeon at both the Philadelphia and the Presbyterial Hospital, died at his home in Philadelphia, January 30, from pneumonia, aged 59.

Edward Bennett, M.D. New York University, New York City, 1862; a surgeon in the United States Army from 1872 to 1875; one of the leading physicians of San Antonio, Texas, for many years, and city physician in 1875, died January 20 at Santa Rosa Infirmary in that city, from uremia, after a long illness, aged 70.

Claiborne A. Duval, M.D. Jefferson Medical College, Philadelphia, 1857; a surgeon in the Confederate service during the Civil War, and several times coroner and health officer of Terrebonne Parish, La., died at his home in Houma, January 23, after an illness of several weeks, aged 73.

Lora D. Dennett, M.D. College of Physicians and Surgeons, Baltimore, 1881, a member of the Biddeford and Saco and York County Medical Associations, died at his home in Saco, Maine, January 30, after an operation for appendicitis and hernia, aged 55.

William Nickolous Klemmer, M.D. Jefferson Medical College, Philadelphia, 1893, a member of the Potter County Medical Society, died at his home in Germania, Pa., January 23, from chronic nephritis, after a long illness, aged 46.

Joseph Luce, M.D. College of Physicians and Surgeons of Chicago, 1885, formerly superintendent of schools, died at his home in Chilton, Wis., January 31, a week after a fall on the ice, in which he fractured his hip, aged 56.

William M. Cameron, M.D. College of Physicians and Surgeons in the City of New York, 1889, died at his home in New London, Conn., January 29, from valvular heart disease, after an illness of several weeks, aged 39.

Thomas F. Gibbs, M.D. University of Georgetown Medical Department, Washington, D. C., 1870, died at his home in Washington, D. C., January 30, from paralysis, after an illness of more than three years, aged 68.

Peter M. McGough, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1878, died at his home in Pittsburgh, January 24, from pneumonia, after a short illness, aged 50.

J. W. Fuqua, M.D. Medical College of Virginia, Richmond, 1861, a surgeon in the Confederate service during the Civil War, died at his home in Vinton, Va., January 27, after a brief illness, aged 71.

William Heverin Hobson, M.D. Jefferson Medical College, Philadelphia, 1895, of Philadelphia, died in the Samaritan Hospital in that city, from typhoid fever, January 30, aged 36.

William Williams Robertson, M.D. University of Maryland School of Medicine, Baltimore, 1864, died suddenly at his home in Baltimore, January 31, from cerebral hemorrhage, aged 60.

David Barry, M.D. Medical College of Virginia, Richmond, 1862, a surgeon in the Confederate service during the Civil War, died at his home in Ashley, Ill., January 31, aged 70.

James H. Bowen, M.D. Jefferson Medical College, Philadelphia, 1857, formerly a practitioner of Devall, La., died in Montgomery, Ala., January 23, aged 77.

Washington L. Jones, M.D. Louisville (Ky.) Medical College, 1875, died at his home in Ensley, Ala., January 26, from cerebral hemorrhage.

George W. Jordan, M.D. New York University, New York City, 1879, died at his home near Rodman, S. C., January 20,

Book Notices

COUNSELS AND IDEALS. From the Writings of William Osler. Selected by C. N. B. Camac, M.D. Cloth. Pp. 277. New York: Houghton, Mifflin & Co. 1905.

Camac has made an excellent series of extracts from Osler's writings and the choice bits are very happily arranged. Some of the group headings are: "Pioneers in Medicine," "Honesty, Truth, Accuracy and Thoroughness in Medicine," "Patient Devotion to Duty and High Ideals," "Medical Education," "Value of Travel," and "Man's Years of Usefulness and How He May Prolong Them." A subject index adds to the value of the book for reference.

THE PRINCIPLES OF RELIEF. By Edward T. Devine, Ph.D., L.L.D., Author of "The Practice of Charity." Cloth. Pp. 495. New York: The MacMillan Co., 1904.

Devine first discusses the fundamental principles which should guide one who grapples with the vital social and economic problem of helping the dependent; then he illustrates both the problem and the methods of relief by case histories and by narration of the organized relief measures taken after some of the great disasters, such as the Galveston flood and the Slocum fire. Charity workers will find this book valuable, as Devine's experience fits him to speak with authority.

DISEASES OF THE HEART AND AORTA. By T. E. Satterthwaite, M.D., Professor of Medicine in the New York Postgraduate Medical School. Cloth. Pp. 504. Price, \$3.00 net. New York: E. R. Pelton.

This book covers the diseases of the heart and aorta. No space is devoted to such subjects as anatomy and physiology of the organ which often preface similar monographs. The text is illustrated by brief histories of numerous cases. It will enable a physician to review heart diseases and to get much important information which can not be found in text-books. Dr. Satterthwaite describes fully his own experience, which gives to the volume the personal flavor desirable in a monograph.

POST-OPERATIVE TREATMENT. An Epitome of the General Management of Postoperative Care and Treatment of Surgical Cases as Practiced by Prominent American and European Surgeons. By N. C. Morse, A.B., M.D., 155 Illustrations and 5 Plates. Cloth. Pp. 468. Price, \$4.00. Philadelphia: P. Blakiston's Son & Co., 1905.

This book will be appreciated by the general practitioner. Too often the surgeon who performs an operation sees the patient only once or twice, and the preparation and after-treatment—which are often vital to the success of the operation—are left to the physician in charge, whether he be prepared or not for all the needs of the case. Morse has made up his book from the methods of the best men in surgery. The matter is clearly presented and the illustrations are good.

HELPS AND HINTS IN NURSING. By J. O. Griffith, M.D., Ph.D. Family Edition. Cloth. Pp. 480. Price, \$1.50 net. Philadelphia: John C. Winston Co.

This book is intended, the author states, for use in homes, as a guide in time of sickness, but as it includes, among other things, directions for administering general anesthetics—ether and chloroform—and for the production of local anesthesia by ethyl chlorid and by hypodermic injection of cocaine, it certainly is not a book which ought to be put in untrained hands. "A little knowledge is a dangerous thing." The chapters on the nurse's relation to the patient, bed making and bed changing, bathing, preparation of food, method of making local applications and of administering medicines are practical and to be commended.

A GUIDE TO ANESTHETICS for the Student and General Practitioner. By T. D. Luke, M.B., F.R.C.S. Second Edition. 45 Illustrations. Cloth. Pp. 155. Philadelphia: J. B. Lippincott & Co. 1905.

The author states in the preface that the increasing popularity of ethyl chlorid as a general anesthetic is the reason for the new edition of this work. Chapter II is devoted to a discussion of the choice of an anesthetic. The book contains many illustrations showing the various apparatus for administering the different anesthetics. The author writes favorably of the chloroform-ether mixture, which, however, has enjoyed greater popularity in Great Britain than in America. He discusses at some length the difficulties likely to arise during administration of an anesthetic and their management. One

chapter is devoted to a consideration of local anesthesia. Luke believes, evidently, that ethyl chlorid is the coming anesthetic, in England at least.

A MANUAL AND ATLAS OF ORTHOPEDIC SURGERY, including the History, Etiology, Pathology, Diagnosis, Prognosis, Prophylaxis and Treatment of Deformities. By J. K. Young, M.D. Illustrated with over Seven Hundred Photographs and Line Drawings, mostly from original sources. Half morocco. Pp. 942. Price, \$12.00. Philadelphia: F. H. Kistleton's Son & Co., 1905.

This ponderous volume, weighing eight and one-half pounds and measuring almost three inches thick, has the appearance of being, and is, padded. The type is commendably large and clear, but some of the space between the lines could be spared, this and the omission of many blank pages would make the book less massive. The publisher's work is less important, however, than that of the author. He says that his work covers the whole field of orthopedics and, so far as we can discover, it does so. Young has taken especial pains with the illustrations. There are over 700 of them, and the examples of characteristic attitudes, deformities, apparatus, methods of treatment, etc., make an atlas of value for the general practitioner.

A MANUAL OF CLINICAL CHEMISTRY, MICROSCOPY AND BACTERIOLOGY. M. Klopstock and A. Kowarsky of Berlin. Translated by T. Wright, M.D. Cloth. Pp. 296. With 122 illustrations, 70 in colors. Price, \$2.25. New York: Robman Co., 1905.

This is a brief, clearly written and up-to-date manual, giving the most convenient and reliable methods of examining the excretions, secretions and blood for pathogenic micro-organisms and for abnormal cellular and chemical constituents. The technique of staining important bacteria which may occur in conjunctiva, upper respiratory passages, urine, feces and skin, and reliable methods of cultivating such organisms, are given in sufficient detail for those who are familiar with bacteriologic principles. One chapter is devoted to methods of bacteriologic examination and the formulae of stains and culture media, and another to qualitative and quantitative chemical examinations of the stomach contents. That recent advances have not been neglected is illustrated by paragraphs on the Morax-Axenfeld bacillus, the paratyphoid bacilli, and methods of cultivating bacteria from the blood.

SURGICAL DIAGNOSIS. A Manual for Practitioners of Medicine and Surgery. By O. G. F. Kilham, M.D. Illustrated by 59 full page plates and by engravings in the text. Cloth. Pp. 449. Price \$4.50. New York: William Wood & Co.

Had the title of this book read a manual for "students" instead of for "practitioners," it would have more clearly defined its field of usefulness, as it is not comprehensive enough for the internist nor for the general surgeon. Its condensed character, its marginal reference and the extensive use of full-faced type in the text to emphasize the essential points make it particularly valuable in student work. The matter is well arranged, and the illustrations, including a number of x-ray plates, are as a rule good. At the end are found a number of tables as a sort of appendix. The heading of one of these, "Identical Symptoms Found in Various Diseases," is decidedly a misnomer as the anesthesia, for instance, of lepra nodosa is not "identical" with the anesthesia of hysteria, nor with that of myelitis, etc., as so classified. There is also a "List of Diseases, Symptoms, Syndromes and Laws Designated by Proper Names" which, although not complete, forms a fitting end to the work.

GALLSTONES AND THEIR SURGICAL TREATMENT. By R. G. A. Movbrink, M.S., F.R.C.S. Second Edition. Revised and Enlarged. Cloth. Pp. 175. Price, \$5.00 net. Philadelphia: W. B. Saunders & Co., 1905.

There are few regions of the body so prolific of disturbances as is the upper abdomen, and not until this region was illuminated by the light of the operating surgeon and the living pathology studied, was the obscurity which surrounded many of them dispelled. In affections of the gall tracts particularly much progress has been made and this progress has been well set forth in this work. How well it has been received by the profession is shown by the fact that the first edition came out the latter part of 1904, and by the end of 1905 a second edition appeared, entirely revised and enlarged by some seventy pages. The entire subject has been very thoroughly covered; anatomy, anomalies, etiology, pathology, symptoms, complications, etc., and last but by no means the least important, a

full description of the technique of the various appropriate surgical operations for this class of cases. The various conditions are exemplified by detailing concrete cases and illustrated by numerous colored and black and white drawings. The author is a practical surgeon of large experience who understands thoroughly the subject of which he is writing and who expresses himself clearly and concisely. The work is a valuable one to the clinician as well as to the surgeon.

THE BARTON FIRST-AID TEXT-BOOK, A Manual for the Student in First-Aid. E. H. H. Hartung, M. D., First Lieutenant and Assistant Surgeon, Ambulance Corps. M. V. M. Arranged and Illustrated by Roscoe G. Wells, Superintendent New England First-Aid Association. Cloth. Pp. 82. Boston: New England First Aid Association.

In view of the number of first-aid manuals worthy of the name now before the public we can find no good reason for the publication of this little book. In it, clearness and accuracy of statement, so essential to the beginner, have been sacrificed by carelessness in style and an unsuccessful attempt at brevity. As notable examples we cite the following:

Page 15: The Lower Extremity consists of the largest and longest bone in the body, called the femur, or thigh bone.

Page 55: Treatment In case of drowning, remove from the water.

Page 56: Cauterization is accomplished by thoroughly burning out the wound. In the case of dog bite never cauterize the wound or kill the dog unless absolutely certain that the dog was mad.

Page 59: Burns produced by alkalis should be treated by the application of acid solutions, such as dilute vinegar in lemon juice.

Page 62: Any substance which is taken into the body that will produce death is a poison.

Page 64: If the sufferer is physically or mentally depressed, such as cold hands and feet, blue lips, the face pale, and a cold perspiration upon the forehead and about the mouth, then a stimulant should be given.

Page 67: The strength of an epileptic in a convulsion is quite powerful.

TEXT-BOOK ON THE PRACTICE OF MEDICINE. For Students and Practitioners. By J. M. French, A.M., M.D., Second Revised Edition. 61 illustrations. Cloth. Pp. 780. Price, \$4.00 net. New York: William Wood & Co.

This book is unlike most text-books in that the author has devoted the first part of the book to a short consideration of the classification and causes of disease, taking up the pathology and bacteriology and describing briefly the subjects of nutrition and metabolism. In the preface it is stated that changes and additions have been made to the text in order to bring the work up to date, yet in the chapters on syphilis no mention is made of the recently discovered *Spirochete pallida*, while in that devoted to yellow fever the *Bacillus icteroides* of Sanarelli is given as the generally accepted cause of the disease. More space than usual is given to tropical diseases. Some of the illustrations are excellent, particularly the charts showing the distribution of guinea-worm and *Filaria* *hominis*, while others, particularly the plate illustrating the parasites of malaria, leave much to be desired. Like most text books on practice of medicine, not enough space is given to treatment. The last part of the work is devoted to a description of the methods of clinical diagnosis, and more particularly to those of laboratory diagnosis, and, while the latter does not exactly "elong in a book of this sort, it is a valuable adjunct to the work.

DISEASES OF THE STOMACH AND INTESTINES. By Boardman Reed. Illustrated. Cloth. Pp. 1021. Price, \$5.00. New York: E. B. Treat & Co., 1904.

This book is founded on lectures to general practitioners. Much stress is laid on the simple methods of investigating diseases of the stomach and intestines, but the best laboratory methods are not neglected. It seems to have been the author's aim to describe the methods which he regarded as best, rather than a multiplicity of ways of doing the same thing. Speculative discussions and unsettled theories are not considered. This treatise must be regarded as a practical rather than as an exhaustive one. The first three lectures are devoted to the anatomy and physiology of the organs, and the following twelve to methods of examination. Stress is laid especially on what can be learned by observation, palpation and percussion. The chemical and microscopic examination of the contents of the stomach is described. Urine examination and what can be learned from it of value to the student of stomach and intestinal diseases is considered in two chapters. The fifteenth chapter contains "a symptomatic guide to diagnosis."

by which is meant an enumeration, under such heads as anorexia, breath fœtor, foul tongue, constipation, etc., of all of the conditions or diseases in which these symptoms occur. Part III, which includes lectures sixteen to thirty-four, describes methods of treatment, embracing dietetics, exercises, electricity, medicinal therapy, mineral waters, etc. In Part IV individual diseases of the stomach and intestines are described. These descriptions are in the main accurate and full. In a series of lectures it is rare to find a balance of parts as well maintained as in a treatise, and this work may be criticised in this respect. Moreover, the lecture style leads to somewhat greater diffuseness of statement than is best in a treatise. Occasionally the author has allowed extraneous matter to creep in, as in Chapter XI, where a page is devoted to better fees for urinalysis and such work. Also, in the chapters on carcinoma of the stomach, gastrocolic fistula, its causes and symptoms are considered before the symptomatology of carcinoma is described. It is not logical to describe a complication such as this before the disease with which it is associated has been discussed.

Miscellany

INTERSTATE RECIPROCITY.

George W. Webster, M.D.

President Illinois State Board of Health; Secretary Council on Medical Education of the American Medical Association.
CHICAGO.

In considering the question of interstate reciprocity in medical licensure we are confronted by several fundamental facts, a want of knowledge of which is at the foundation of most of the present nebulous, hazy, chaotic ideas in regard to this subject. These are the facts:

First—Everything relating to the whole subject of medical education, including preliminary entrance requirements, the license and control of the practice of medicine, belongs to the state; its regulation and control is an exercise of the general "police power" of the state; it is one of the state's rights with which the federal government has nothing whatever to do.

Second—The State Board of Health, or the examining or licensing board in each state, is, in view of the authority vested in it by the legislature, the only body authorized to determine the condition or terms under which physicians are licensed to practice in that state. This body determines the character of the entrance requirements, the length and character of the medical course, the subjects embraced in the medical curriculum, the time to be devoted to each, the character and scope of the examination, the equipment of the medical college in order to be in "good standing" with the board. The state alone, each for itself, through its examining board, has the sole right to establish and to maintain medical educational standards.

Third—These laws and rules are not made and executed and standards maintained in the interests of the medical profession, but for the protection of the people, it being an inherent, constitutional right with which they are guaranteed—the right to "life, liberty and the pursuit of happiness." This fundamental fact is almost universally overlooked, both by the medical profession and, more especially, by those seeking special legislation in favor of special sects, such as osteopaths and the like.

Fourth—In accordance with its recognized constitutional right, each state has established its own standards, there being no uniformity between them, or at least there was formerly none, but at the present time there is comparative uniformity among some of them.

Fifth—Each of the 157 medical colleges in the United States has adopted a standard of its own for conferring the degree of M.D., but this does not confer the right to practice, as this would be delegating the authority of the state to the medical college.

Sixth—That various associations of medical colleges, state boards, etc., have established standards, but they also have no right to determine and to enforce standards for any state, as this would be delegating the power of the state to some organization, and this would not be tolerated.

Under these circumstances, what can be done to bring about exchange of licenses on a fair and equitable basis? A fair exchange can be made only on equal terms. Let us see what has been accomplished. Take Illinois for example. Illinois has determined that an applicant for licensure must have, as a preliminary entrance requirement, a high-school education or its equivalent, must have attended four courses of instruction of not less than seven months each in four separate calendar years in a medical college, the character and equipment of which is determined by the board, must have received a diploma after graduation from said institution and must have also sustained a satisfactory examination in all the branches usually embraced in the medical curriculum, the number of questions in each subject corresponding to its time value in the curriculum. Illinois offers to reciprocate with any state having equal requirements. On this basis Illinois at the present time does reciprocate with the following states: Iowa, Michigan, Wisconsin, Indiana, New Jersey, Maryland, Maine and Kansas.

In other words, here is practical reciprocity on the only rational basis: equal requirements, uniformity in entrance requirements, uniformity in length and character of the medical course and uniformity in the scope and character of the examinations. Uniformity in legislation is also desirable.

How can this scheme of reciprocity be extended so as to embrace all or nearly all the states? I would propose the following:

It should be done through the organized profession, as embodied in the American Medical Association and by its Council on Medical Education. This council should appoint the following committees:

First—A subcommittee on entrance requirements, comprised of, say, ten members, representing the medical colleges, the universities, the high schools and the boards of examiners. Let this committee be given at least a year, or, if necessary, a longer time, to study the whole subject and then to report to the Council on Medical Education what the minimum entrance requirements should be.

Second—A subcommittee of five or ten members for each of the twenty-three subjects in the curriculum, the committee to be selected from the leading educators in each subject and including, if possible, members of examining boards on each subcommittee. Let each of these committees establish a minimum standard and determine how many hours should be devoted to the subject, how much of this time to lectures, to recitations, to laboratory work and to clinics, and what kind of equipment, teachers, etc., are required to teach the subject properly, and the order in which the subject should be taught in relation to other subjects.

Third—An additional committee to determine whether other subjects, such as business methods, history of medicine, etc., shall be added to the present curriculum, and, if so, how much time should be devoted to them and where in the course they should be placed.

The committees, aggregating, in round numbers, 250 of the leading medical educators of the United States, would report to the educational council and it in turn would codify the work, and thus would be established standards of such high order of merit that no one would be able to criticize it successfully. The council would also provide for a plan of regular periodical, perhaps decennial, revision of this standard. Each state and medical society adopting this standard would be entitled to representation in the revision convention.

Then let the council urge the legislative committee of the American Medical Association to work in the interests of uniformity in medical legislation for the states through the legislative committees and examining boards of all the states.

To establish reciprocity it is only necessary for the states to adopt the standards of the Council on Education. As soon as a medical college adopts this standard let it be enrolled as an institution in "good standing," both with the council and with all examining boards that have adopted this standard. As soon as two states have adopted this standard there is reciprocity on a fair, rational, equitable basis. In a very short time a large number of states and the leading medical colleges will have adopted this standard and the others will be gradually brought up to it.

ADVANTAGES OF THE PLAN.

The advantages of this plan are:

1. It secures the co-operation of the American Medical Association and of the medical colleges.
2. It secures the co-operation of the high schools, the medical colleges, the universities and the state licensing boards in the establishment of standard requirements for entrance to the medical colleges.
3. The proposed standards will be more likely to be adopted because all parties concerned in their adoption are participants in their preparation and establishment.
4. It will bring the American Medical Association and the licensing boards into closer and more harmonious relationship.
5. It will bring the American Medical Association and the medical colleges in closer and more harmonious relationship.
6. It not only provides for high, reasonable and uniform standards for the present; but it provides for regular periodical revision by those adopting it and, therefore, interested in its maintenance and perpetuation.
7. It will bring into co-operative harmony the legislative committee of the American Medical Association and the legislative committees of the states.
8. After definite, uniform standards are adopted, it will be easier to secure the enactment of uniform, favorable, desirable legislation.
9. It establishes interstate reciprocity on a reasonable basis.

Tubercle Bacilli.—Piery and Mandoul (*Arch. Gén. de Méd.*, 1905, No. 19), have studied the different types of the tubercle bacillus in the various forms of the disease and summarize their general conclusions as follows: 1. Koch's bacillus takes various forms in the sputa of consumptives; the homogeneous, moniliform, para-moniliform and diplobacillus types are especially noticed. 2. These various forms are derived one from the other and are due to differences of coloration of the peripheral layer of the bacillus which sometimes is tinted like the central framework (homogeneous type), and sometimes, on the other hand, appears more feebly colored (paramoniliform type), and still others remain uncolored (moniliform type). 3. The morphologic and numerical variations in the sputa are in relation both to the evolution of the tuberculous process and to the clinical form of the disease. 4. Their study permits of following clinically the different stages of the tuberculous process and contribute to the diagnosis of the clinical form. 5. On the other hand, the morphology and number of bacilli in the sputa have no prognostic value. 6. The bacteriologic formula (morphology and number of bacilli) of the different forms of pulmonary tuberculosis undergoes modifications in hemoptysis bearing chiefly on the number of bacilli which is generally diminished by the dilution of the blood.

Retention of Salt as a Factor in Obesity.—More and more attention is being given to the reputed possibility of influencing dropsy by the regulation of the intake of salt as the favorable experiences of the French in this line are being confirmed by others. Labbé (*Presse Médicale*, No. 101, page 809) has recently been endeavoring to apply this same theory to obesity, explaining excessive corpulence as due in part to retention of salt with corresponding retention of water. He put two obese patients on the same diet, not salted, but each was given 15 gm. of salt a day, with which to season his food to taste. The amount left in the salt cellar showed how much had been used; the amount eliminated was also determined every day. He found that one patient retained over 40 gm. and the other over 100 gm. of salt in the course of a month. There was no trace of kidney trouble in either. On the basis of this rather limited and questionable experience he theorizes that chlorid retention must be an important factor in the production of obesity, also that the therapeutic restriction of fluids in obesity is irrational, ineffectual and even dangerous, as the tissues become dehydrated and consequently more saturated with salt. This explains, he says, the disturbances sometimes noted when the obese are kept on a dry diet. He declares that they should be encouraged to drink freely, but that the intake of salt should be restricted, and he proceeds to build up somewhat unwarranted conclusions as to the mechanism of his assumed "salting" of the obese. His communication does credit to his powers of imagination working on such scanty material, even if time should prove the correctness of his views in regard to the retention of salt in obesity.

The Irrational Stand of the Antivivisectionist.—The enormous sacrifice of animal life to provide the meat for the extra feasting at Christmas is the subject of comment by the *Medical Press* (London). "Man's merriment in this instance," it says, "is inseparably connected by long tradition with an enormously devastating sacrifice of life among the lower animals. . . . How many antivivisectionists, whose mental attitude commands our sympathy although not our respect, have ever paused to consider the inwardness of the Christnastide slaughter? Have they ever looked analytically on this picture of the butchers' and the poulterers' shops on the one hand and on that picture of the scientific laboratories on the other? Here we see a vast sacrifice of life, representing a vast amount of cruelty, with the sole purpose of providing folk with extra food for their Christmas enjoyment. There we see carefully planned research carried out under the most humane conditions known to science, with one single end and aim, namely, the preservation of human life from suffering and from death. The great fundamental distinction between the two sacrifices of the life of the lower animals in the two instances under consideration is that one is intended merely to satisfy the greedy maw of jovial man, while the other is intended to save him from bodily ills of all kinds. How can a sane, intelligent condone the butcher and condemn the vivisectionist? If anyone said of the butcher what is said every day in the week about the vivisectionist, the antivivisectionist would retort that the objections were sentiment gone mad. Yet all the while he swallows the camel of animal food, but strains with restless and incessant bitterness against the goat of vivisection. The life of the lower animals is subservient to him for food, for labor, for clothing, for ornament, for anything and everything in his narrow world, in short, save for the one high purpose of acquiring the knowledge of preserving the health and the lives of his fellow-men. As men grow more intellectual and reasoned in their outlook, so will they be likely to regard the question of vivisection in its true perspective."

The Successful Practitioner Reads.—There is something radically wrong with the man who has "no time to read." If he hasn't the time he should take the time, just as he should to eat and sleep. How else can he know what is going on in the medical world and what advances are being made? Does it ever occur to him that the reason he lost that case yesterday was because he is already behind the times—even though he is out of college less than five years? The fact that very likely would have saved the life was in the magazine. . . . which he never took the trouble to open. No matter how successful he may be, sooner or later he will be replaced in the affections and confidence of the community by young Jones, who has hard scrambling enough now, . . . but who is forging to the front, because he has "time to read." It's a strange thing, but you never hear of any men of the first eminence in the profession who have no time to read. Yet they must be busy or all signs fail, for how else did they attain their eminence except by knowing things that others did not know and doing things that others could not do. Read? Why, these men are continually reading. In their "spare moments" they not only keep up with the profession, but keep ahead of it. . . . "No time to read?" My dear friend, it isn't so. The trouble is that you are too lazy; . . . you had rather take a nap or have a "quiet smoke" after the labors of the day or spend your time in some other idle way than to get right down to this building business—this making of better doctors. Gradually, how gradually you can hardly say, you get "out of the notion," and now you delude yourself with the belief that you are "too busy!" My poor friend, you are going to have time enough "for reading" or anything else after a bit. Really, wouldn't it be better to take a little time right now, and keep "in the swim?" "Work?" Of course, it is, but it pays.—*Am. Jour. Clin. Med.*

Antiquackery Campaign.

The German Antiquackery Society, whose official title is the *Deutsche Gesellschaft zur Bekämpfung des Kurfischertums*, appeals for support to "all who regard enlightenment of the public in regard to the true nature of quack practices as an imperative task for the civilization of modern social life, and who wish to protect themselves and their fellow-men against injury in time of sickness." It urges all such to promote the aims of this antiquackery movement in the name of hygiene and public welfare. Subscriptions for this German society

should be sent to Dr. G. Siefert, Charlottenburg, Hardenbergstrasse 39, Germany. The annual membership fee is 3 marks, or about 75 cents a year.

ANTIQUACKERY JOURNAL.

The society has its own organ, a twenty-page monthly, called *Hygienische Blätter*, edited by Dr. Carl Reissig, Hamburg 5, Germany, subscription about 50 cents a year, including foreign postage. It is written in popular style and writes up quacks and irregulars of all kinds, as well as nostrums, in much the same way as we are doing in the department of Pharmacology. The *Hygienische Blätter* is designed to be circulated among the general public, to be left on the tables in physicians' waiting rooms and elsewhere, while at the same time it contains articles suggesting ways and means in which physicians can aid in combating quackery. It is sent free to all members of the society. The October number suggests that physicians should take the pains to learn the past record of quacks and show them up. One of the more prominent German "nature healers" recently referred to the ranks of charlatans in Germany as "containing former jailbirds, frauds of all kinds, rakes and prostitutes," and the police records, when looked up, frequently prove the truth of this assertion.

NOSTRUMS.

One department of the *Hygienische Blätter* is devoted to secret remedies and nostrums, relating instances of injury from them and the results of analysis by experts.

QUACKERY BEFORE THE COURTS.

Criminal proceedings against "nature healers" and quacks of all kinds are recorded, with details, in another department, with an occasional table summarizing the various sentences passed by the courts for fraudulent or dangerous quack practices or for injury from such. The latest list includes 82 cases, in which fine or imprisonment was imposed. Previous criminal proceedings are recorded against many of the names.

ANTIQUACKERY EXPOSITION.

The antiquackery movement in Germany obtained great impulse from the exposition of quack methods which was held at Breslau in 1904 and again at Meran in 1905, in connection with the "Naturforscher Congress." The exhibition is in eight sections: fake ads, nostrums, wholesale quack measures, original remedies, "non-toxic" nostrums, non-operative treatment, electro-homopathy, magnetism, hypnosis, and the "nature healers." The collection has recently been accepted by the government and added to the collection of "means of instruction to promote the public health," for which a central station has been established to loan the collections as deemed advisable. The collection includes a number of the original formulas of various familiar nostrums, and, arranged beside the fake medical literature, are the articles and decrees from the police and other authorities showing them up, or showing the unsavory details of the careers of the originators. Both exhibitions attracted crowds of medical and lay visitors, and they are proving one of the most effectual means to enlighten the public in regard to the dangers of nostrums and quacks in general. The *Hygienische Blätter* was first circulated in connection with the first of these exhibitions. The beginning of an international antiquackery movement was recently described on page 122.

Queries and Minor Notes

CAUSE OF INCREASED URINATION AT NIGHT.

— IOWA, Jan. 20, 1906.

To the Editors:—What conditions might cause the amount of urine excreted during the night to exceed that excreted during the day? The patient is an unmarried woman, aged 55. She is poorly nourished, pale, and her occupation is an indoor one. She has chronic constipation, which yields to mild laxatives and diet. The arteries are sclerotic, the heart is slightly enlarged, but compensation is good. Neither casts nor albumin can be found in the urine. The family history is distinctly "cardio-nephritic." Since the patient drinks fluid only between 6 a. m. and 6 p. m., and 24 hours in 1 day, nocturnal urine to exceed diurnal, I have been led to the conclusion that she is probably in the incipient stage of Bright's disease, despite absence of albumin and casts. The patient is greatly bothered by frequent nocturnal urination. Medical factors might account for increased frequency, but hardly seems to me for increased quantity of urination at night. There is nothing in the pelvic to cause trouble except slight retroversion.

To emphasize: This patient drinks nothing after 6 p. m. She excretes more urine at night than in day time. Can you justify, on these premises, a diagnosis of deficient renal permeability? C.

ANSWER.—The age of the patient, her poorly nourished condition, the sclerotic state of her arteries, and the enlarged heart with, presumably, increased arterial tension, and in addition, her family history which you characterize as "cardio-nephritic," indicate that this is a case of incipient chronic indurative nephritis or contracted kidney.

The increased urination is not at all rare in this condition, and frequently constitutes, as you correctly surmise, an early sign of Bright's disease. The absence of casts from the urine does not militate against this diagnosis. It is possible, however, that if you will examine many specimens with very delicate tests, you will sooner or later find a little albumin. Senator expresses himself as follows in regard to this matter: "This form of nephritis is frequently overlooked or neglected in the beginning. It develops very gradually, with signs of cardiac hypertrophy and increased arterial tension and usually with some polyuria, and occurring especially at night (pollakiuria)." In regard to the form of nephritis that you are dealing with, which is presumably of the arteriosclerotic variety, the urinary signs are especially liable to be absent for a long time after increased urination, with cardiovascular signs, make their appearance.

So far as the treatment is concerned, careful attention to the gastrointestinal tract and measures directed toward keeping the blood pressure down will be efficacious in preventing a rapid development of this disease.

ACETANILID IN BROMO-SELTZER.

NORTH PLATTE, N.B.

To the Editor:—Recently I was called to see a man who had taken a heaping tablespoonful of bromo-seltzer. The heart was missing about every third beat, he was cyanosed, and the extremities were cold. The pulse was thready, irregular and intermittent. When I first entered the room I was struck by the dirty appearance of the patient's hands, but on examining them more closely I found they were not dirty but cyanotic. The lips had the same dirty bluish appearance and the ashy gray color of the face reminded me of a cadaver. The temperature was 96 F. The man was bordering on collapse, and I think would have died had not his stomach been emptied and stimulants administered.

D. T. QUIGLEY, M.D.

WASHINGTON, D.C., Dec. 7, 1905.

To the Editor:—Can you give the formula of bromo-seltzer? I find that it is very extensively and freely used, and I think that it would be interesting to know what it is that so many people are taking so frequently, and in such large quantities.

B. M. RANDOLPH.

ANSWER.—We have had analyses made of Bromo-Seltzer as sold in original bottles to the trade. These analyses show that 100 parts of the effervescent salts contain:

Potassium bromid	10.53 parts.
Acetanilid	4.58 parts.
Caffein	1.20 parts.

Assuming an average dose of the article—a teaspoonful—to weigh 76 grains (5.0 gm.) each dose would contain:

Potassium bromid	7 grains (0.5 gm.)
Acetanilid	3 grains (0.2 gm.)
Caffein8 grains (0.05 gm.)

Since a half ounce of this preparation is often taken at a dose, and since many, women especially, are taking it daily, it is anything but "harmless."

STATES THAT RECIPROCATE.

— IOWA, Jan. 31, 1906.

To the Editor:—What states have reciprocity agreements with Wisconsin, Illinois and Iowa?

A. B. C.

ANSWER.—There is reciprocity between Wisconsin, Indiana, Michigan, Ohio, Iowa, Kansas, Illinois, Nebraska, Kentucky, Maryland, Georgia, Oklahoma, South Carolina, New Mexico, North Dakota and District of Columbia, on the basis of qualifications as adopted by the American Confederation of Reciprocating Medical Examining and Licensing Boards. Requirements by the various states are so different that the question can not be answered by a general statement. Any physicians desiring to register in another state should correspond directly with the secretary of the licensing board of that state.

MIDWIFERY IN PENNSYLVANIA.

DENT'S RUN, PA., Feb. 1, 1906.

To the Editor:—Can a person without a license or certificate legally practice midwifery in Pennsylvania? B. E. MERRILL, M.D.

ANSWER.—There is no definite statement regarding this in Pennsylvania law. Most states require an examination. Further information may be obtained by writing to Dr. H. S. McConnell, New Brighton, secretary of the State Board of Medical Examiners.

State Boards of Registration

COMING EXAMINATIONS.

MAINE State Board of Registration of Medicine, City Building, Portland, March 13. Secretary, Wm. J. Maybury, Saco.

CONNECTICUT Medical Examining Board, City Hall, New Haven, March 13-14. Secretary, Charles A. Tuttle, New Haven.

MASSACHUSETTS Board of Registration in Medicine, State House, Boston, March 13-14. Secretary, Edwin B. Harvey, Boston.

Arkansas January Report.—Dr. J. P. Runyan, secretary of the State Medical Examining Board of the Arkansas Medical Society, reports the written examination held at Little Rock, Jan. 9, 1906. The number of subjects examined in was 7; total number of questions asked, 61; percentage required to pass, 75. The total number of applicants examined was 44, of whom 28 passed and 16 failed.

* Second examination.

** Third examination.

The following questions were asked:

Surgey.

1. Give symptoms and differential diagnosis of Pott's disease. What is scoliosis, lordosis, kyphosis? 2. How would you treat?

case of gunshot wound of the lower jaw with a great deal of loss of soft parts and with from one inch to one and one-half inches shattered and blown away? 3. Describe two of the most common dislocations of the hip joint and give the differential diagnosis of dislocations and intercapsular fracture. Give function of ilio-femoral ligament in dislocations of hip. 4. Describe accurately the proper method of locating the fissures of Rolando and Sylvius on the skull. 5. Give diagnosis and pathology of calcitones in bladder and ducts. 6. Describe the course and treatment of a case of infection of the hand and extending up the arm. What are liable to be the results? 7. Describe various fractures involving the elbow joint. Give the important points to be observed in treatment of fractures near joints to prevent excessive callus and ankylosis. 8. Give differential diagnosis between fracture of neck of the humerus and the head of the scapula. Give treatment of the latter. 10. Describe accurately an amputation of the leg at the junction of middle and lower thirds.

BACTERIOLOGY.

1. From what two bacteria most the bacillus tuberculosis is distinguished? 2. Name five bacteria that do not stain by the Gram method. 3. What is Koch's law? 4. Name one bacillus that can not exist in air. 5. How can malaria be diagnosed from typhoid fever microscopically?

ANATOMY.

1. Describe the scapula. 2. Describe the middle meningeal artery, giving origin, branches, and the structures supplied. What difference, if any, in structure of artery as compared with other arteries? 3. Describe muscles of adduction and abduction of thigh, giving origin and insertion of each. 4. Describe the elbow joint and mention bones and ligaments forming it. 5. Describe the bones of the ear. 6. Describe the submaxillary, parotid and suprarenal glands. 7. Ligate the subclavian artery at outer third. Give collateral circulation after. 8. Mention in order the muscles over McBurney's point, and give directions of fibers in each. 9. Describe the spleen. 10. Describe Littre's gland.

DISEASES OF WOMEN.

1. Give differential diagnosis of oophoritis of right side, and appendicitis. 2. Give cause, diagnosis and treatment of pelvic peritonitis; pyosalpinx. 3. Do a vaginal hysterectomy. 4. Give reasons advanced for Alexander's operation. Describe the operation in detail. 5. Mention symptoms and diagnosis of fibroid tumors of the uterus.

EYE AND EAR.

1. Give differential diagnosis between keratitis and iritis. Give treatment of each. 2. Define astigmatism; synchchia; hypopyon; myopia. 3. What muscle or muscles rotate the eye outward and downward? 4. Give three characteristic symptoms of glaucoma, and one important remedy. 5. Give symptoms and treatment of hemorrhage in internal ear.

SKIN AND VENEREAL DISEASES.

1. Give differential diagnosis of eczema and psoriasis, and give treatment of the latter. 2. Differentiate between syphilis, psoriasis and leprosy in the palm. 3. How would you treat herpes zoster? 4. What is meant by gonorrheal orchitis, and how would you treat it? 5. Diagnose and treat secondary syphilis.

CHEMISTRY.

1. Define an element; a molecule; an atom. 2. What are atomic weight, specific gravity, valance? 3. Name the normal constituents of urine. 4. How would you detect sugar in urine? How estimate the daily quantity? 5. What is formed when phosphorus burns? 6. What is the color of iron under dry respiration? 7. How would you detect the presence of starch? 8. Give formula for permanganate of potassium. What poisons is it said to antidote? 9. What is fermentation? 10. What is Paris green? Give treatment for poisoning by it.

HOMEOPATHIC PRACTICE AND THERAPEUTICS.

1. Differentiate hepatization of lower lobe of lung and pleuritic effusion. Name one prominent remedy, with indications, for each condition. 2. Describe a clinical case, giving symptoms, in which you would prescribe mere, coral. 3. Name and give indications for two prominent remedies in la grippe. 4. Outline your treatment of cholera infantum. Give indication for the remedies you would use. 5. Name three remedies used in cholera, giving characteristic indications for each. 6. How would you treat uræmic convulsions? Give remedies and dose. 7. On what indications would you prescribe belladonna in throat affections? 8. Describe a clinical case, giving symptoms, in which you would prescribe apocynum. 9. Give stomach symptoms calling for musc. leprodonum, and hence. 10. Name two heart remedies, giving indications for their use.

MEDICAL JURISPRUDENCE.

1. What is somatic death? Molecular death? 2. What changes in the skin would indicate death? 3. How would you determine whether death was due to drowning, or to some other cause and the body subsequently submerged? 4. Define illusion, hallucination, delusion. 5. What is the history of hydrocyanic acid poisoning? What is the antidote?

OBSTETRICS.

1. Describe the lochia. How long does it last? 2. Name the normal presentations of the vertex, and give diagnosis of the one most frequent. 3. Give cause and treatment of after-pulsus. 4. Give choice, and reason therefor, and the manner of administering an anæsthetic in an ordinary case of labor. When would you not use it? 5. Describe minutely the operation for Cesarean section. 6. Describe "birth-marks," and give their cause. 7. What do you do to prevent rupture of the perineum? 8. Describe fully the first care and dressing of the child. 9. Give cause, symptoms, dangers and treatment in a severe case of ante-partum hemorrhage.

GENERAL PATHOLOGY.

1. Describe catarrhal inflammation. 2. Define atrophy. Give varieties of atrophy. 3. What pathological changes may elicitates ulcer? 4. Name the most common pyogenic bacteria. 5. Where and what are the pathological changes in bulbar paralysis? 6. Give the possible causes of occlusion of the bile duct. 7. Describe yellow

or crude tubercle. 8. What is thrombosis? Describe the manner of its formation. Give some of the lesions in chronic interstitial nephritis. 10. Explain the development of pus corpuscles.

REGULAR PRACTICE AND THERAPEUTICS.

1. Give diagnosis of pneumonia. 2. Differentiate neuritis and rheumatism. 3. Differentiate diphtheria and follicular tonsillitis. 4. What is the significance of prolonged expiration? 5. Give the physical signs of a cavity of the lungs in pulmonary tuberculosis. 6. Denote therapeutic incompatibility; chemical incompatibility. 7. Outline the treatment of uremia. 8. Compare opium and belladonna as to action on the heart. 9. What serious results may cause from indiscriminate use of acetanilid? 10. Give treatment for ulcer of the stomach. 11. Give name and dose of each of five official preparations of opium.

ELECTIC MATERIA MEDICA, THERAPEUTICS AND PRACTICE.

1. Give names and doses of three general anodynes. 2. Give the official name and the composition of Fowler's solution. 3. Write a prescription containing drugs that are chemically incompatible. 4. What precautions should be used in giving medicines by the hypodermic method? 5. Describe the manner of giving sulphuric ether. 6. In what diseases would you give salicylic acid? Dose of same. 7. Write a prescription for general debility. 8. What remedies would you use in obstinate vomiting, due to pregnancy? Doses of same. 9. Give treatment for night sweats. 10. Describe and treat a case of rubella.

PHYSIOLOGY.

1. Describe the white blood corpuscles, and give their source and functions. 2. What changes are produced in the air by respiration? 3. Describe the normal heart sounds. 4. Describe the lymphatic system. 5. Give the time, and mode of eruption, of the temporary set of teeth. 6. Differentiate between tonic and clonic muscular contractions, and give an example of each. 7. What conditions produce variation in the normal temperature of the body? 8. Describe the human blood. 9. What gives color to the skin? 10. What are the causes of death from asphyxia?

Vermont January Report.—Dr. W. Scott Nay, secretary of the Vermont State Board of Registration, reports the written examination held in Montpelier, Jan. 9-11, 1906. The number of subjects examined in was 12; total number of questions asked, 90; percentage required to pass, 75. The total number of applicants examined was 2, both of whom passed. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
University of Louisville	(1905)	85.9
Jefferson Medical College	(1905)	84.7

The Public Service

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending February 3, 1906:

Bushnell, George E., surgeon, granted thirty days' leave of absence.
Gandy, Charles M., surgeon, granted ten days' leave of absence.
Clarke, Joseph T., surgeon, granted three months' leave of absence.
Roberts, Wm., asst.-surgeon, ordered to proceed from Fort Hamilton, N. Y., to Fort Jay, N. Y., for temporary duty.
Grissinger, Jay W., asst.-surgeon, leave of absence extended ten days.
Newlove, George, contract surgeon, reported at New York for duty as surgeon of the transport *McClellan* on his next voyage to the Philippines.

White, J. Samuel, contract surgeon, left Fort Snelling, Minn., for New York City, to accompany the First Infantry thence to Philippine service.

McCallum, Francis M., contract surgeon, accompanied troops from Fort D. A. Russell, Wyo., to Seattle, Wash., and returned.

Brown, Wilmont E., contract surgeon, ordered from Fort Walla Walla, Wash., to Fort H. Barracks, Idaho, for temporary duty.

Dickenson, Clarence F., contract surgeon, ordered to accompany the Second Infantry from Fort Logan, Colo., to San Francisco, Cal., and thence to Philippine service.

Dillon, G. F. Barker, contract surgeon, ordered from Fort McDowell, Cal., to Army and Navy General Hospital, Hot Springs, Ark., for treatment.

Kuhn, Charles F., contract surgeon, arrived at Fort William H. Seward, Alaska, for temporary duty.

Waddell, Ralph W., dental surgeon, returned to Fort Leavenworth, Kans., from temporary duty at Fort Washable, Wyo.

Whinnery, Jenn C., dental surgeon, arrived at Fort Wright, Wash., for temporary duty.

McAlister, John A., dental surgeon, returned to Presidio of Monterey, Cal., from leave of absence for two months.

Macy, Fred S., contract surgeon, left Allegheny Arsenal, Pa., for duty at Fort Adams, R. I.

Van Kirk, John H., contract surgeon, returned to Fort Sill, Okla., from march with Field Artillery to Fort Sam Houston, Texas.

Navy Changes.

Changes in the Medical Corps, United States Navy, for the week ending Feb. 3, 1906:

Rothganger, G., surgeon, detached from the naval hospital, Norfolk, Va., and ordered to the naval hospital, New York, N. Y.

Farenholt, Surgeon A., detached from the *Raleigh* and ordered to the *Oregon*.

Freeman, G. F., passed assistant surgeon, detached from the naval station, Cavite, P. I., and ordered to the *Indefatigable*.

Wheeler, L. H., assistant surgeon, ordered to the naval station, Cavite, P. I.

Rixey, P. M., surgeon general, commissioned surgeon general and chief of the Bureau of Medicine and Surgery, Navy Department, with the rank of rear admiral from Feb. 5, 1906.

Gatewood, James B., surgeon United States Navy, designated by the acting secretary of the navy, is detailed as a member of the joint board of medical officers of the army and navy, appointed by orders of Jan. 11, 1906, War Department, to consider improvements in the first-aid dressings and uniformity of equipment for the medical departments of the two services, vice Surgeon Charles P. Stokes, United States Navy, relieved. War Department, January 31.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended January 31, 1906:

Kallich, P. C., surgeon, reassigned to duty at Portland, Me., Quarantine Station.

Cofor, L. B., P. A. surgeon, letter granting leave of absence for twenty days, from January 13, amended to read twenty days from January 20.

Grubbs, S. D., P. A. surgeon, granted twenty-one days' leave of absence from February 2.

Anderson, J. F., P. A. surgeon, resigned to duty in the Hygienic Laboratory, effective January 23.

Hobby, W. C., P. A. surgeon, relieved from duty at Honolulu, Hawaii, and directed to proceed to San Francisco Quarantine Station and assume command of the service, relieving P. A. Surgeon S. S. Cummings.

Corput, G. M., P. A. surgeon, directed to proceed to Kenner and other places in Louisiana for special temporary duty, on completion of which to rejoin station in New Orleans, La.

Corput, G. K., P. A. surgeon, granted five days' leave of absence from January 16, under provisions of Paragraph 191 of the Regulations.

McLaughlin, A. J., P. A. surgeon, relieved from temporary duty at Berlin, Germany, and directed to rejoin station at Naples, Italy. Colvare, Geo. L., assistant surgeon, granted leave of absence for two days from January 22, under provisions of Paragraph 191 of the Regulations.

Stearns, W. L., pharmacist, granted five days' extension of leave of absence from January 27.

Walterus, Mathias, pharmacist, granted thirty days' leave of absence from February 15.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague, have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended February 2:

SMALLPOX—UNITED STATES.

Arkansas: Fort Smith, Jan. 13-20, 1 case.
California: San Francisco, Jan. 13-20, 14 cases.
Colorado: Wilmington, Jan. 13-20, 1 case.
Florida: Alachua County, Jan. 20-27, 3 cases; Gadsden County, 1 case; Jacksonville, 8 cases; Polk County, 1 case.
Kentucky: Covington, Jan. 20-27, 8 cases.
Louisiana: New Orleans, Jan. 20-27, 4 cases.
Maryland: Baltimore, Jan. 20-27, 1 case.
Nebraska: South Omaha, Jan. 13-27, 8 cases.
Ohio: Cincinnati, Jan. 13-26, 7 cases; Dayton, Jan. 20-27, 1 case.
South Carolina: Camden, Jan. 13-20, 1 case.
Wisconsin: Appleton, Jan. 20-27, 8 cases.

SMALLPOX—ISRAEL.

Porto Rico: San Juan, Dec. 1-31, present.

SMALLPOX—FOREIGN.

Argentina: Buenos Ayres, Oct. 1-31, 47 deaths.
Canada: New Brunswick: Queen's County, Jan. 9-18, present; Sydney County, Jan. 9-22, 106 cases.
China: Shanghai, Dec. 21, present.
France: Paris, Jan. 6-13, 27 cases, 1 death.
Ecuador: Guayaquil, Dec. 17-24, 2 deaths.
India: Bombay, Dec. 26-Jan. 2, 7 deaths; Calcutta, Dec. 9-16, 20 deaths; Karachi, Dec. 25-31, 3 cases, 1 death; Madras, Dec. 16-29, 15 deaths.
Italy: General, Jan. 4-11, 22 cases.
Mexico: Tuxpam, Jan. 16-23, 1 death.
Russia: Odessa, Dec. 30-Jan. 6, 16 cases, 2 deaths; St. Petersburg, Dec. 25-30, 10 cases, 3 deaths.
Spain: Barcelona, Jan. 1-19, 1 death; Cadiz, Dec. 1-31, 1 death.
Turkey: Constantinople, Dec. 17-31, 8 deaths.

YELLOW FEVER—UNITED STATES.

Louisiana: Jefferson Parish (Kenner), Jan. 28, 1 case.

YELLOW FEVER—FOREIGN.

Ecuador: Guayaquil, Dec. 17-24, 8 deaths.
Mexico: Merida, Jan. 14-29, 2 cases, 1 death; Vera Cruz, 2 cases, 1 death.

CHOLERA—FOREIGN.

India: Calcutta, Dec. 9-15, 61 deaths; Madras, Dec. 16-29, 10 deaths; Raunoon, Dec. 16-23, 13 deaths.
Russia: Government, Lomza, Dec. 23-30, 4 cases, 1 death; Ostrow, 1 case, 1 death; Plock, Dec. 4-17, 50 cases, 20 deaths; Siedlitz, Nov. 23-Dec. 25, 22 cases, 10 deaths; Warsaw, to Dec. 18, 9 cases, 5 deaths.

PLAGUE—FOREIGN.

Africa: Portuguese East Africa, Chinde, Nov. 12-18, 1 case, 1 death.
India: Bombay, Dec. 26-Jan. 2, 9 deaths; Calcutta, Dec. 9-16, 21 deaths; Karachi, Dec. 24-31, 20 cases, 15 deaths.
Japan: Shimonoseki, to Dec. 23, 5 cases.
Mauritius: Dec. 8-20, 15 cases, 12 deaths.
Peru: Callao, Jan. 11-20, 1 case, 1 death; Lima, 1 case, 1 death; Molendino, 1 case; San Pedro, 4 deaths.

Medical Organization

Illinois.

MONTRIE COUNTY MEDICAL SOCIETY. Physicians of Montrie County met at Sullivan recently and effected organization with the following officers: President, Dr. W. E. Stedman, Sullivan; vice-president, Dr. Howard Hamilton, Bethany; secretary and treasurer, Dr. Zerfass, Sullivan, and censors, Drs. W. P. Davidson, Sullivan; John D. Hardinger, Gays, and William H. Davis, Bethany.

Good Results from Organization.

CLATSOP COUNTY (ORE.) MEDICAL SOCIETY.—The secretary of this society, in a recent communication, says: "Our society is small, but includes every licensed practitioner in the county; we meet every two weeks, have excellent papers followed by discussion, and in addition to taking up subjects that are of interest to the profession, have interested ourselves in matters that pertain to the public welfare. Previous to the formation of our society the local physicians were scarcely on speaking terms with each other; now every man is an active member, we meet socially as well as professionally, and our only regret is that we did not get together many years ago."

The Physician's Relations to His Professional Associates.

As a merchant takes account of stock each year in order to ascertain the condition of his business and whether he is progressing or retrogressing, so each of us should from time to time interrogate himself, and see whether we are doing the best and the most with our abilities and opportunities. Let each one of us occasionally ask himself a few pertinent questions and endeavor to answer them frankly and truthfully. He who can not be true to himself is hopeless, for he can not be true or honest to anyone, or under any circumstances be considered absolutely reliable.

As a member of a learned and liberal profession, what is my relation to that profession and to the community in which I live? Am I living so as to bring credit and repute to myself and to my profession? When I consider my brother physicians in my vicinity, is my heart free from envy, hatred and malice, am I dwelling at peace with them, and if not—why? Is the fault entirely theirs? Have I not allowed some false rumor or the idle talk of some irritable patient to prejudice me against a brother practitioner, and have I taken the trouble to verify the statements made to me? In fact, do I know him sufficiently well to judge him in any particular? Have I met him socially and professionally, and have I tried to find out his good points and his professional ability, and to be at peace with him, or have I ignored him, failed to attend my county medical society because he was likely to be there, and because I was foolish enough to believe the stories carried to my ears and so did not wish to associate with him? Have I treated him fairly and as I would have him treat me, under similar circumstances?

Toward the physicians younger than myself, or to those who have more recently come here, have I extended the hand of fellowship, and have I welcomed them in a brotherly way; or have I criticized and belittled them and endeavored to make their path as rough, as unpleasant and as impossible as I could? Have I acted the part of a broad minded, well educated and skillful member of the greatest of the liberal professions, and thus brought credit and repute to that profession as well as to myself, or have I acted the part of a jealous, petulant man, and through my derogatory comments and criticisms—which were in the main untrue—brought discredit to a brother practitioner and to myself and my profession?

The science and art of medicine is progressing rapidly in these days, and to keep pace with it, that physician who will be properly equipped so that he may give his patients the very best that medical learning can provide, must be ever a student, must read and study carefully the writings of many men. Have I done this, or have I simply stagnated, remained stationary and allowed the stream of medical knowledge to go by me? Am I as well equipped as I should be to attend to the wants of my patients? Have I been giving to my patients remedies the composition of which I am ignorant, and thus possibly endangering some one's life, or have I used that knowledge and judgment in prescribing which my patients assume that I possess? In general, am I as good a doctor as I should be?

These and many other questions are such as we should ask ourselves from time to time. How many who read them and truthfully catechise themselves can answer them satisfactorily? Particular stress is laid on the personal relation of the phy-

sician to his professional brethren, for it is the most important relation in professional life. Without association with others of his kind, progress and education are very difficult, nay, well nigh impossible.

The solitary and isolated life of the physician leads him toward two deadly dangers: egotism and narrow-minded ignorance. In the course of his work he meets with sick people—his patients—and but seldom with his brother physicians. His patients rank him high and compliment him, not knowing whether he is doing his work as well as he should or not; and unconsciously he elevates himself in his own estimation, and too often looks down on and belittles his fellows. Thus there is lacking the incentive to study, to progress; he overestimates his own knowledge and attainments. Frequent association with other physicians who are doing as much or more work, and as good or better work than he is doing himself, is the very quickest and surest way of removing these elemental delusions of grandeur and of re-establishing in such a physician a more healthy mental tone.

Society Proceedings

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

Centennial Meeting, held at Albany, Jan. 30, Feb. 1, 1906.

The President, DR. JOSEPH D. BRYANT, New York, in the Chair.

Cleveland Urges More Medical Knowledge for Public.

This meeting marked the reunion of the two medical bodies of New York state after a separation of twenty-five years. Ex-President Grover Cleveland was one of the speakers and took as his theme the further education of the public in matters medical. He referred to the old-time doctor who surrounded his methods of diagnosis and treatment with much mystery. This habit has been largely done away and is now the property of the quack. Mr. Cleveland urged that the medical profession go further and tell the patient more about what is the matter with him, the causes of it, how it may be relieved and what particular method is used in the particular case. He felt that the time is ripe for this step.

Bryant's Happy Address.

The president DR. BRYANT, in his address said that the medical profession of the country regards this occasion as one of the most important in the history of its existence. "For a painfully long period of time the open contention existing in the medical profession of this state has robbed the profession of the significant influence in medical and public matters freely accorded to much less beneficent and potent bodies of men. Bodies illly inclined to salutary measures and encouraged chiefly because of their forceful organization, even in the attainment of self-seeking aims, have badly defeated the wholesome endeavors of the disorganized opposition of magnanimous and earnest medical desire. Too often, indeed, in the past divided medical counsel or half-hearted medical support has failed to beget the respectful consideration, on the part of those in authority, due to the justice of a cause championed by the medical profession. How often, in fact, has it happened within the easy recollection of us all that we have fittingly been told by those in authority: 'When you can agree among yourselves, then come to us for aid!' This reason or excuse, whichever it may have been, can no longer be regarded as available for the diplomatic purposes which it has served in the past. The enrolled regular physicians of the state—not less than 6,500 in number—are to-day a united body of attentive medical men, laboring in common for commendable interests and beneficent causes. The medical profession of the state can now take hold with a firm, confident grasp in support of wholesome public-spirited propositions and of medical advance with the full consciousness of the fact that their united desire, or their confirmed opinion, will constitute a bulwark of moral force not to be misjudged nor indifferently considered. Please note the fact, my friends, that I refer to general medical and public propositions, meaning general professional and public duty, not private nor personal propositions relating more often than otherwise to private or personal desire, too frequently strongly tinged with self-seeking motives.

"So long as the medical profession shall contribute its part to the interests of the public good, the public servants will heed its admonitions and respect the logic of its appeals. But when unwise personal desires or clanish purposes shall proselyte patriotic or disinterested efforts, then will the hold on public esteem be loosened and medical appeals to public confidence become of much less avail or respectful consideration entirely forfeited. In every community, as well as in the state at large, there are broad and fertile fields for the encouragement and practice of general and special good. Therefore, 'Be ye not weary in well doing,' as the reward for all such labor as this is munificent and ever exercising its influence in behalf of those who actively foster healthy sentiments."

He said that the membership of the society was 6,500, and urged that every regular physician in the state should be a member in good standing. Every one thus enrolled should recognize that he himself is an active unit—if he shall choose so to be—and of as much importance as is any other individual unit of the organized body. "And when he shall have recognized these facts, there yet remains another of far greater significance to be known, the fact that this relationship carries with it profound responsibility—the exacting creator of onerous duty, fortified, let us hope, with abundant love for just causes; duty to ourselves and to our professional brother, to our profession, and to the people at large, and to all things that shall glorify our calling and add to the enlightenment of the world."

Dr. Bryant praised the "extraordinary zeal and infinite patience of the Joint Committee of Conference, to which some time ago the fortunes of the independent medical bodies were mutually and wisely entrusted. Although the members of the committee have bided slowly, they have bided intelligently and for all time, and in strict accordance with the letter of the law regulating such matters. Much yet remains to be accomplished under the order of the court before the control of the affairs of the great body can be relegated by the ad interim House of Delegates to the completed organization. I hope that all who are engaged in the completion of this great work will co-operate promptly and cheerfully with those now vested by the court with the construction of the legal framework required for the purpose."

The election of officers was announced in THE JOURNAL last week.

Prize Money Provided.

DR. LUCIEN HOWE, Buffalo, sent \$1,500 to the society as a nucleus for a fund to provide prizes for essays.

An excellent scientific program was carried out.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Regular Meeting, held Dec. 7, 1905.

The President, DR. RICHARD C. NORRIS, in the Chair.

The Uterus and Ovary of Chronic Neurasthenia.

DR. ROBERT L. DICKINSON, New York, presented the results of a study based on one hundred cases.

The associated lesions and their frequency were as follows: Chronic ovaritis, chiefly microscopic, was found in nearly all the cases. Endometritis, usually cervical, was present in the majority of cases (61) and was seldom accompanied with thickening of the endometrium. A high degree of sclerosis of the vessels of the uterine walls and of those of the endometrium was sometimes discovered in cases of long standing, and the venous enlargements were many. Certain hypertrophies about the vulva were noted in the majority of cases (65). In the bladder, congestion of the trigone was frequent (about 40 cases). In the rectum, catarrh, congestion and atony were present in a large number of cases. Pelvic symptoms were prominent, and lumbar pain was constant. In almost all of these cases the pelvic disorder was coincident, not causative. Dickinson found that correction of moderate abnormalities of structure and function by prolonged local treatment or by operation lessens pelvic pain very little and betters the general condition not at all. Treatment should be directed almost entirely to the general condition. Operation on pronounced pelvic lesions is warrantable in a few selected

cases, such as persistent and exhausting hemorrhages and the larger tumors, and, if thorough-going, brings about a cure, revolutionizing the general condition in a very small percentage of cases. Anatomic cure frequently fails to bring about symptomatic cure.

Dickinson excluded from his list the congenitally delicate, hysteria, melancholia, milder cases, and all not subject to long observation. Many were old office habitués. All complained of sacral pain; 46 complained of cramps at the periods; 43 of irritable bladder; 24 of leucorrhœa, and 10 were entirely free from any pelvic disturbance, except headache. The averages of antelexion and retroversion usual in gynecologic office practice were found. Among 21 retroversions there were 10 operations, all anatomic cures, but obtaining only partial symptomatic relief. All were glad they had it done a short time after operation, but only two were entirely happy about it two years after. Chronic ovaritis, present in gynecologic practice in some 15 per cent. of cases, was seen with surprising frequency. Of 20 confirmed neurasthenics (some outside this series whose ovaries were studied at oeliotomies), 20 had distinct microcystic ovaritis. Long-continued tension resulting in alterations in the walls of the vessels of the endometrium and uterine walls was emphasized in this class of cases. In 4 cases intractable menorrhagia called for hysterectomy. The holding up of varicosities of the broad ligament and bladder wall on a pessary explained some improvements. Endometrium, uterine wall, ovary, bladder base, rectal mucosa—all suffered from disturbed vasomotor balance, persistent venous engorgement and sometimes arterial spasm and thickening. Masturbation, evidenced by pronounced corrugated hypertrophies of the labia minora and prepuce and fourchette and enlarged and flabbed meatus (found in 1/3 of all cases in ordinary office gynecologic practice), was detected in 2/3 of the pronounced neurasthenics.

What was new in this small series of cases was the analysis, from the standpoint of the gynecologist, of the relations of pelvic disease to long-standing neurasthenia; the claim of the frequency of chronic ovarian changes, of chronic congestions of the trigone and lower bowel, and of vulvar hypertrophies; the statement that latero-cession and thickening of the left utero-sacral ligament and broad ligament with left-sided ovaritis, in the absence of adhesion, is always due to chronic proctitis; and figures bearing on the small percentage of cures after operation. In conclusion, the author laid great stress on regulation of activities, on training in outdoor life initiated in wisely-conducted sanitariums.

DISCUSSION.

Dr. F. X. DERCUM agreed with Dr. Dickinson that in the great majority of cases pelvic disease and neurasthenia, when co-existent, are coincident, and that there is no causal relation between them. One factor, however, to be considered is that neurasthenia, pure and simple, is synonymous with chronic nervous fatigue. The symptoms are characteristic and definite, and the affection constitutes a well-defined fatigue neurosis. Associated with this exhaustion is irritability. In consequence there is in neurasthenia an undue reaction of the nervous system to either peripheral or somatic impressions. For this reason local pathologic conditions might bring about undue reaction in neurasthenia, while in a state of nervous health such conditions may attract no attention. He entirely agreed with Dr. Dickinson that in the chronic and aggravated type of neurasthenia, in women, pelvic symptoms are prominent. He formulated his conclusions on the subject of neurasthenia in women as follows: 1. That neurasthenia may exist independently of any pelvic disease. 2. That neurasthenia and pelvic disease may exist independently in the same patient. 3. That when pelvic disease and neurasthenia co-exist, the pelvic symptoms may be more readily recognized by the patient and, therefore, become more prominent, because in neurasthenia the reaction of the nervous system to abnormal and pathologic impressions is exaggerated.

Pelvic disease never causes true neurasthenia. It might produce general ill health, but the nervous symptoms present are never the symptoms of neurasthenia. That various signs of nervous weakness are present in serious local or general disease, weakening the entire organism and, with it, the nerv-

ous system, is not surprising. To this state he applied the term of spurious neurasthenia or neurasthenia symptomatice. This is seen in chlorosis, phthisis, syphilis, in the various diseases of the blood, in malignant disease, in the toxemias and in other grave disturbances of nutrition. The nervous symptoms directly due to pelvic disorders, he said, are exceedingly limited. While it was true that there is present pelvic pain, pain referred to the back, to the hips, to the thighs, with indications of general ill health, these symptoms can not be grouped as a separate nervous disorder, but are part of the pelvic disease itself.

He believes that a dispassionate consideration of the subject leads to the conclusion that the surgeon should operate for surgical indications only. The minor pelvic troubles disappear on the institution of rest, full feeding, massage and the like and when the general health of the patient has been brought to a physiologic level.

Dr. BARTON COOKE HIRST said that this experience has taught him that the gynecologist does better if he forgets that the patient under examination is a neurasthenic, or if he does not know it. In his opinion, the function of the specialist in pelvic disorders is to examine and report on the pelvic organs and, if disease is found, to give the appropriate advice without necessarily taking into account the patient's general condition, except as a contraindication to operation. If pelvic disease coincident with neurasthenia is discovered, it should be remedied, if possible, in order to put the patient in a better condition for being cured of her neurasthenia, but without expecting that the gynecologic treatment will directly benefit the neurasthenia. Long-continued local treatment for minor pelvic conditions, which might fasten the treatment habit on the woman, should be avoided.

Dr. CHARLES K. MILLS said that the neurasthenic condition should be lost sight of and attention and treatment concentrated on the pelvic disorders. His experience with neuro-gynecologic cases has taught him that in many of the cases the conditions presented to the neurologist and gynecologist are dependent on neurotic or neuropathic tendencies in the individual. In the study of aggravated nervous symptoms apparently dependent on disorders of the pelvic organs, the exact cause should be determined, whether it lay in the pelvic condition or in the nervous constitution. In a large majority of cases the explanation is to be found in a study of hereditary predispositions. Attention should be directed to the presence of any real disorders of the pelvic organs, in connection with other treatment. Neurasthenia, like hysteria, he said, is not a disease of the uterus or its appendages, but is primarily a disease of the nervous system. Attention should be directed to the relief of an inherited or of an inherited plus an acquired condition of the nervous system.

Dr. J. M. BALDY stated that few competent gynecologists of to-day operate on aggravated cases of neurasthenia. He thinks that, if, when these cases come to the gynecologist, he could forget that they had pelvic symptoms, both the patients and the gynecologists would be fortunate. He thinks that an examination of as many non-neurasthenic women will disclose much the same condition as Dr. Dickinson found in his patients. With Drs. Mills and Dercum, he does not believe that neurasthenia is caused by pelvic lesions, although it might be aggravated in some few cases. Operation, except in a very few well-selected cases, can only do harm. Beyond falling into the hands of an operating gynecologist, he knows of but one equal misfortune for these much-afflicted individuals, and that is to fall into the hands of a rest-cure neurologist. Dr. Baldy stated his fear that his emphatic views concerning the treatment of neurasthenia are not in accord with those of the majority of neurologists and gynecologists. Rest is needed, but only as applied to the nerves, and the rest needed is rest from the irritating elements which are wrecking those organs. The fatigue is purely a nerve fatigue and not a muscular fatigue. Let no man, however, who wished to cure his patient make the mistake of assuming that rest meant rest of the muscles and general physique. This can not be brought about abruptly nor in the same manner in all classes of patients, but the principle can be applied to all. Force the patient, in spite of all pretexts, protests or sympathies, to an

active out-of-door life, with proper hours of rest and regulated diet, milk and eggs constituting a large element in the latter. The "rest-cure," he declared, in any of its phases, is pernicious, and sanitariums are the last places in the world for these cases.

DR. WILLIAM G. SPILLER said that he does not believe that neurasthenia in most cases can be cured by treatment of the generative organs. He is in accord with the view that in the presence of mild disorders of the reproductive organs it is better not to give any treatment to these organs, because attention directed to them aggravates the neurasthenic symptoms. If, however, the symptoms of disease of the degenerative organs are severe, he advises treatment of the lesions, because, until they are treated, there is little hope of improving the neurasthenia. Dr. Spiller believes oophorectomy to be one of the most serious operations that can be performed on a neurasthenic woman, not from a surgical point of view, but he stated that the neurasthenic women who have had ovaries removed are often hysterical and are among the most difficult patients to treat. He believes that the ovaries have some effect on the general health of the individual, especially in younger women. He scents the possibility of a relationship existing between disorders of the reproductive organs and brain tumor, although the effect of a brain tumor in arresting menstruation had been repeatedly observed. Regarding functional disorders, he said, it must be acknowledged that severe disease of the ovaries leading to removal might awaken a latent neurosis which otherwise might never become manifest.

DR. JOHN G. CLARK said that, in the minds of many physicians, neurasthenia and hysteria are almost interchangeable, notwithstanding the wide difference between the two conditions. Charcot described a type of hysteria associated with ovarian pain and located a point at the intersection of a line drawn from the anterior superior spines of the ilium and the outer border of the left rectus muscle, which has been designated as "Charcot's point." This class of patients complain constantly of pain in this area. The point does not correspond to the situation of the ovary, and, as a result of this fallacy, innumerable ovaries have been removed in the past with the thought that the pain would be relieved. He is convinced that this pain had nothing to do with the ovaries. The word neurasthenia, he thinks, is used to cover a multitude of evils, serving about the same purpose for various bizarre nervous symptoms that the word malaria does for an unexplained fever. Asthenia, with nervous manifestations, is classed under the term neurasthenia. From a clinical standpoint, the gynecologist might safely consider these cases under one of three headings: (1) Pure neurasthenia of congenital origin, with morbid pelvic introspection, but without even a microscopic organic lesion; (2) a neurasthenia which is coincident with a given organic lesion, but not dependent on it, although it may greatly exaggerate it; (3) a neurasthenia entirely dependent on an organic lesion.

The patient with neurasthenia of hereditary origin should never have gynecologic treatment, but should be turned over to the neurologist or to any other person capable of diverting the unhealthy stream of her imagination. Such a patient naturally complains of all the ills to which flesh is heir, and if the generative organs become the point of her introspection, the gynecologist can not cure her by operative interference. Such a person, becoming the subject of an operation, is likely to establish the operative habit, which has been very appropriately called "mania operativa minor."

In the second class of cases, neurasthenia coincident with some pelvic lesion, the nervous symptoms are usually exaggerated by the pelvic disease; consequently, in such a case this trouble is likely to be improved, although a cure of the neurotic phase of the case is naturally not to be expected. In the third class of cases, neurasthenia incident to pelvic lesions, he said, there can be but one viewpoint, and that is the sooner the pelvic lesion is relieved the greater will be the chance for perfect cure of the neurasthenia. If such a case drifts on for weeks or months, the neurasthenic habit might be so completely fixed by the time operation is done that months or years might elapse before such a woman could recover her nervous equilibrium. Such cases are represented by the vari-

ous hemorrhages of the menopause. In such cases suffering from recurring hemorrhages of the menopause or from some new growth, and, with increasing anemia developing, intense neurasthenia should have immediate treatment to stop the hemorrhage, even if hysterectomy is necessary. Such cases make ideal recoveries.

In the treatment of all three of these classes of cases Dr. Clark believes that the skill of the surgeon is tested thoroughly. Every phase of the patient's past life should be traced concerning the various possible manifestations of neurasthenia. The chief point from the operative standpoint is the past history. Gynecologists of experience look on oophorectomy as one of the gravest operations. Unfortunately, young women of 20 or 23 years of age, who have been operated on for double pyosalpinx, frequently drift into the hands of the neurologists and there is formed an unjust prejudice against the operation or the operator on account of the postoperative sequelae. Under the stress of pathologic conditions, however, the gynecologist has been forced to intervene. A large proportion of these patients, however, after having passed through a stormy premature menopause, regain, to a considerable extent, their nervous equilibrium and might complete a very satisfactory life work. The day for the removal of ovaries on symptomatic grounds has passed, and the man who exhibits at society meetings, as has been done in the past, specimens of ovaries, which are vaguely classed as cystic or sclerotic, lays himself open to the severest condemnation. Dr. Clark believes that the gynecologists are greatly indebted to the neurologists for pointing out the radical difference between hysteria and neurasthenia. Gynecologists, as well as other surgeons, have been able to render a reciprocal service by demonstrating the value of operative treatment in the proper classes of neurasthenias.

DR. CHARLES P. NOBLE thinks that the majority of gynecologists believe that neurasthenia and hysteria exist not only independently of trouble in the pelvis, but concomitantly with it. He believes firmly in the existence of reflex disorders and has seen many cases of return to health after correction of some pelvic condition. With this one exception, he is in hearty accord with all the neurologists said on general principles. In his opinion, the gynecologist should deal with a patient with neurasthenia or hysteria associated with pelvic disease as he would deal with an insane patient presenting these disorders. If the pelvic condition threatens the patient's life, it should be corrected. It is then easier to solve the question of any remaining difficulty. In his experience there is no way in the city whereby a neurasthenic in poor circumstances can be treated by the rest cure. In the few places where they are admitted they receive no benefit in the general wards. Regarding the treatment of patients with nervous symptoms, Noble disproves of local treatment for functional symptoms without local lesions in young unmarried women. He believes that there are instances of lives being ruined by these young women becoming tied to physicians' offices and developing psychoses with regard to their sexual organs.

DR. WILLIAM E. ASHTON referred to true neurasthenia and to nervousness dependent on local lesions, and thinks that until the neurologist can positively differentiate between neurasthenia and neurasthenoid conditions it is unnecessary for him to consult with the surgeon. He thinks no neurologist is justified in placing such patients on rest-cures without knowing the condition of the pelvic organs. While he does not believe that a diseased pelvic organ produces essential neurasthenia, he holds that a large number of women not benefited by rest-cures are afterward permanently cured by operation for some gross pelvic lesion. He emphasized the fact that unless the actual condition of the pelvis is known the patient should not be treated by rest-cure. In neurasthenic or pseudo-neurasthenic cases he believes that in the presence of gross pelvic lesions operation should be done for a cure, whether or not the neurologist is certain of the diagnosis. In operation for a cure, the operation should be carefully considered. He believes the removal of enlarged cystic ovaries in a neurasthenic woman is unwise. The resection of the diseased portion alone allows the possibility of pregnancy and the retention of menstruation.

DR. J. MADISON TAYLOR thinks that in the consultations of the gynecologist and the neurologist little would be left for the general practitioner to do. He thinks that in the cases showing arrested development good results will be secured as opportunity is given for better development.

Therapeutics

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Scabies.

The successful treatment of scabies, according to E. O. Huntington in *New York Med. Jour.*, depends on the destruction of the parasite that causes it; and as this parasite inhabits those parts covered by thin, tender skin, it is difficult to reach them. The flexor surfaces of the wrists, the axillae, genitals and the spaces between the fingers are the sites of predilection for the acarus. Huntington's treatment consists in directing the patient to take a warm bath, during which time the infected areas are to be gently scrubbed with tincture of green soap and chalk or powdered pumice, followed by the application of sulphur ointment. This may be used alone or combined with balsam of Peru in proportion to the severity of the dermatitis. If pustular lesions are present they may be touched with carbolic acid, which may be neutralized with alcohol previous to applying the ointment. After applying this ointment twice a day for three or four days a cure will be effected. The patient should then be directed to take another warm bath and to make a complete change of clothing. All bed clothing should also be thoroughly disinfected. If dermatitis still persists, any bland ointment will suffice to heal it.

Groat, in the same periodical, in addition to the precautions outlined above, recommends thymol as a safe and sure parasiticide and antipruritic. It may be used in combination with sulphur ointment, as it is liable to irritate the skin when used alone. He also recommends pure ether and alcohol in equal parts as an efficient parasiticide in scabies, but it is irritating where breaks in the integument exist. To allay the dermatitis the ointment of benzoated zinc oxid is recommended in combination with the parasiticide.

In females and children, and where delicate regions are involved, the following combination is of value:

R. Thymol	3i iss	4-10
Ung. sulphuris	5i iss	10
Ung. zinci oxid.	3i	30
Lanolini, q. s. ad.	3iii	90

M. Ft. unguentum. Sig.: Apply locally three times a day.

In the foregoing either the thymol or the sulphur will kill the parasite. When much eczema exists, or excessive itching, the sulphur should be omitted and the zinc ointment increased, and about one-half dram of menthol added. If the patient objects to the use of ointments the following lotions are of value:

R. Thymol	3i iss	10
Alcoholis	3iii	90
M. Ft. lotio. Sig.: Apply locally three times a day. Or:			
R. Thymol	3i iss	10
Spts. etheris	5v	20
Alcoholis	3i iss	75

M. Ft. lotio. Sig.: To be applied locally three times a day. Or:

R. Menthol	gr. lxxv	5
Thymol	3i iss	10
Alcoholis q. s. ad.	3iii	90

M. Ft. lotio. Sig.: Apply locally.

After applying one of the foregoing lotions locally for a few days the following ointment should be applied:

R. Ung. zinci oxid.	3ii	60
Ichthyol	gr. lxxv	5
Lanolini q. s. ad.	3iii	90

M. Ft. unguentum. Sig.: Apply locally.

The author emphasizes the value of thymol as a parasiticide and as an anesthetic to the peripheral nerve endings, thus allaying the itching.

The best remedy to employ after the parts are properly prepared, according to Alger, is betanaphthol with sulphur as a good substitute. He employs it in the following combinations:

R. Betanaphthol	5i ss	6
Saponis mollis	5ss	15
Liq. petrolati	5i ss	45

M. Ft. unguentum. Sig.: Apply locally twice a day for four days.

After these applications a bath should be ordered and a change of clothing.

Other combinations are recommended by some authorities as follows:

R. Sulphuris sublim.	5i	4
Balsami Peruviani	5ss	2
Lanolini	5i	30

M. Ft. unguentum. Sig.: Apply locally. Or:

R. Hydrag. chloridi corros.	gr. i	106
Ammonii chloridi	5ss	2
Alcoholis	5vi	24
Aque rose q. s. ad.	3vi	180

M. Ft. lotio. Sig.: Apply locally.

As an ointment the following, containing the oil of eade may be used:

R. Sulphuris sublim.			
Olei cadini, aa.	5ii	8
Crete prep.	5i ss	10
Saponis viridis			
Lanolini, aa.	5i	30

M. Ft. unguentum. Sig.: Apply locally twice a day.

In the "Handbook of Local Therapeutics" the following combinations are recommended:

R. Sulphuris flores.	5ii	8
Betanaphthol	5i	4
Balsami Peruviani	5i	30
Lanolini q. s. ad.	5ii	60

M. Ft. unguentum. Sig.: Apply locally.

Potassa sulphurata may be employed in the form of a lotion in the following strength:

R. Potass. sulphurata	5iv	16
Aque	5viii	240

M. Ft. lotio. Sig.: Apply locally two or three times a day.

And as an ointment in the following strength:

R. Potass. sulphurata	5ss	2
Lanolini	5i	30

M. Ft. unguentum. Sig.: Apply locally twice a day.

Constipation in Infancy.

According to Robert Hutchison, the consequences of constipation in children are sometimes of a serious nature because of the toxic effects as well as the mechanical effects in the intestine. The patients become dull and languid, and suffer from headache, anorexia and insomnia. They become restless, nervous and irritable. In some instances he speaks of an intermittent pyrexia as being the result, simply, of constipation.

In the treatment of constipation the diet must be carefully regulated and proper exercises instituted, giving especial attention to the exercise of the abdominal muscles as well as massage and cold douching or spraying to the stomach.

In some cases, simply increasing the amount of water drunk by the child will be sufficient to correct the trouble. In the greater number of cases, however, aperients are necessary. He emphasizes the importance of persistent, systematic, continuous treatment and the spasmodic intermittent treatment.

Cascara is recommended, as a combination containing aloes, as follows:

R. Tinct. aloes	m. xv	1
Sodii sulphatis	5i	4
Syrupi seminae	5i	4

M. Sig.: At one dose at bedtime. Increase the dose gradually until two movements daily are obtained.

This combination may be continued for some weeks and gradually diminished.

In some cases a preparation which is supposed to stimulate the action of the liver is advised, and for this purpose he rec-

ommends mercury in the form of the hydrargyrum cum creta given in addition to the foregoing preparations:

If mucus or worms are present this author advises rhubarb combined as follows:

R. Pulv. rhei.....	gr. x-x	30-65
Hydrarg. cum creta.....	gr. i	96

M. Ft. cachet No. i. Sig.: One at bedtime.

The rhubarb exercises a tonic or astringent effect on the mucous membrane and thus checks the secretion of mucus. The important point in the treatment is to select a tonic laxative and to administer it persistently for several weeks or months. This selection should depend on the reaction of the patient, as some patients react much better to one preparation than will another. The object to be obtained is to educate the bowels, which, according to the author, can be accomplished in the child but not in the adult.

CATARH OF THE INTESTINE.

In cases of catarrh of the intestine, whether constipation or diarrhea is present, he recommends alkalies to dissolve the mucus. The following combination is of value:

R. Potassii bicarb.....		
Potassii citratis, aa.....	gr. v	30
Tinct. nucis vomice.....	℥ i	96
Infus. gentiane coq.....	℥ i	8

M. Sig.: At one dose in a little water, before meals.

As an aperient the following may be used:

R. Pulv. rhei.....	gr. viii	50
Sodii bicarb.....	gr. x	65
Hydrarg. cum creta.....	gr. i-ii	06-12

M. Ft. cachet No. i. Sig.: At bedtime every night, or in mild cases every second night.

After following this treatment for two weeks the administration of tonics is required, which must include iron.

Medicolegal

Destruction of Life During Parturition.

The Court of Criminal Appeals of Texas reverses, on the appeal of Evans vs. State, a judgment of conviction for destroying the life of a child during parturition. It says that, in its opinion, the evidence was wholly insufficient to support the conviction. It failed to show with any degree of satisfaction or conclusiveness that the child was born alive, or was alive at the inception of its birth. Without such proof the evidence was not sufficient to sustain the conviction.

Alcohol in Medicines and External Remedies.

The United States commissioner of internal revenue says in a recent ruling, that the internal revenue laws of the United States do not contain any provision as to the quantity of alcohol that may be used in the manufacture of medicines. The ruling in Circular 673 (reported on page 1025 of THE JOURNAL of Sept. 30, 1905), has no application to external remedies, such as liniments, in the preparation of which alcohol is used. No special tax is required to be paid under these laws for the manufacture and sale of liniments.

Second Physical Examinations in Injury Cases.

Section 873 of the New York Code of Civil Procedure provides that: "In any action brought to recover damages for personal injuries, where the defendant shall present to the court or judge satisfactory evidence that he is ignorant of the nature and extent of the injuries complained of, the court or judge shall order that such physical examination be made," etc. In the personal injury case of Orlando vs. Syracuse Rapid Transit Railway Co. an order for the physical examination of the plaintiff was obtained on affidavits which showed that the defendant was ignorant of the nature and extent of his injuries. There was no suggestion in the affidavits that a physical examination had already been made at the request of the defendant, with the plaintiff's consent, without any order therefor. But the plaintiff's counsel thereafter presented to the justice who made the order an affidavit showing such former examination, and after hearing counsel on both sides the justice vacated the order made by him for a physical examina-

tion on the ground that it had been imprudently granted. No affidavit, apparently, was made, in answer to the one presented to the justice, disputing the fact of the former examination or excusing the omission to show that fact in the affidavits on which the order for an examination was made. The Fourth Appellate Division of the Supreme Court of New York states that, under these circumstances, it can not say that the order setting aside the former order for an examination was erroneously granted. If it was claimed a second examination was necessary for any special reasons, the facts relating thereto should have been made to appear by the defendant, in the affidavits on which the first order was granted or in answer to the application to set the same aside.

Contract of "Medical Institute" Utterly Void.

The Supreme Court of Washington says that the case of Deaton vs. Lawson was brought to recover money paid under a contract for treatment purporting to be with the officers of a certain medical institute and the physician in charge, apparently signed "S. M. Inst.," which treatment was taken for only a day or two. The findings and entire testimony in the case, however, clearly showed that this was the personal contract of the defendant, who it was found, was not entitled to practice medicine under the laws of the state, not having a license to so practice. The reference in the body of the contract to the medical institute, its officers, and the physician in charge, and the claim of the defendant that he signed the contract as secretary for the regularly licensed physician employed by the medical institute, were but so many pretenses to evade the laws of the state. It was admitted in the pleadings that the medical institute was owned, operated, managed, and controlled by the defendant; in other words, he was doing business under that name. It was further shown that the physician was not a party to the contract, and was in no manner obligated to perform it. It was found, and he himself testified, that he had no connection directly or indirectly with the medical institute, had nothing to do with the making of contracts or the fixing of fees, but was simply employed on a salary. If the claim of the defendant that he signed the contract as secretary for the physician should be sustained, there would be no contract at all, as the record clearly showed that he had no authority in that behalf. Stripped of all subtleties and pretenses, this was neither more nor less than a contract on the part of the defendant to render professional services for the plaintiff, a contract he could not perform without violating the laws of the state. The contract was, therefore, against public policy, and was utterly void. A contract to render professional services is personal and non-assignable. No person can perform or tender performance except the person therein named, without the consent of the other party to the contract. Inasmuch as the defendant could not perform his part of the agreement without violating the laws of the state, there was no consideration for the alleged contract or the payment of the money thereunder, and the plaintiff was entitled to recover the money so paid, so long as the contract remained executory (still to be performed).

Compensation of Health Officers.

Section 2660 of the Kentucky statutes provides that "physicians appointed as health officers for cities, towns and counties shall receive reasonable compensation for their services to be allowed by the councils, trustees or the county courts," etc. The Court of Appeals of Kentucky says, in Graves vs. City of Paducah, that the health officer is an officer of the city, and must be paid by it. The statute does not fix the amount of his compensation, further than that it shall be reasonable, and be allowed and paid as other city officers' salaries are paid. Perhaps no other officer of the city renders services of such fluctuating and uncertain value as does its health officer. Absence of epidemics and a general disposition on the part of the population to cleanliness of their premises would relieve this officer of the necessity for rendering any services, other than perfunctory. In that event his compensation would doubtless be but little. On the other hand, where there occur epidemics of contagious diseases, requiring the health officer's services to a considerable extent, his compensation would be increased in proportion. It will be difficult, if not impossible

to show in advance just what such services might be worth. If the municipality charged with their payment fixes in advance a schedule of fees, as it should, or even fixes a sum per annum which would seem to cover the ordinary services rendered or required to be rendered by the health officer, unless it could then be shown that the allowance or salary so fixed is unreasonably small, it ought not to be interfered with, especially after the officer has accepted it throughout the term as payment. In the case of Taylor vs. Adair County the fiscal court had provided a salary of \$40 per annum to the health officer of the county. The Court of Appeals held that such a sum was inadequate and unreasonably small for the services rendered in that case. While it was there said that the fiscal court could not in advance fix the salary of the health officer, the expression was meant to convey the idea that generally it would be impracticable to attempt to do so, rather than that there was want of legal authority so to do. On the contrary, it was conceded that the power to fix the salary in advance not only existed, but that it was expedient that it be exercised in some just form. The city council, not the witnesses, are directed to fix the reasonable compensation for the services rendered. Before an allowance for such services, or the fixing of a salary for that officer, not unreasonably small on its face will be set aside, it must clearly appear that the allowance or salary is unreasonable and inadequate. Not by a mere preponderance of testimony from those in the profession as to what is customarily charged for such services by physicians, but from all the circumstances and evidence, it should appear that there has been a palpable abuse of discretion, amounting to injustice, by the board or tribunal vested with the duty and power of fixing the compensation.

Current Medical Literature

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

American Medicine, Philadelphia.

January 2.

1. Problems in the Diagnosis and Treatment of Puerperal Infection. B. C. Hirst, Philadelphia.
2. *Intestinal Hemorrhage as a Fatal Complication in Amebic Dysentery and Its Association with Liver Abscess. R. P. Strong, Manila, P. I.
3. *Tropical Liver Abscess. J. M. Coffin, U. S. A.
4. *Cyst of Kidney Simulating Ovarian Cyst. W. Krusen, Philadelphia.
5. Treatment of Pulmonary Tuberculosis in China. N. Y. H. H. Wey, China, N. Y.
6. *Diphtheria Antitoxin Effective in Scarlatina. J. H. Lopez, Philadelphia.
7. Chronic Enlargement of the Tonsils as a Factor in Etiology. C. P. Nelson, Westbrook, Minn.

2. **Intestinal Hemorrhage Complicating Amebic Dysentery.**—Strong reports four cases in which the fatal termination was due to this complication. The fact that in all the cases large liver abscess coexisted shows, Strong thinks, that a close connection exists between intestinal hemorrhage and the hepatic condition. The idea that the destruction of such large amounts of liver tissue may sometimes bring about serious functional disturbances of this organ and lead to a condition which predisposes to hemorrhage must certainly be considered. While it is probable that more extensive observations will show that fatal intestinal hemorrhage in amebic dysentery may occur quite independently of liver abscess, the cases to which Strong refers seem to show that when hemorrhage occurs in cases complicated with such hepatic disease it is likely to be very severe and that the bleeding is likely to recur. It is possible, also, that the occurrence of multiple intestinal hemorrhages in amebic dysentery occasionally may be of some importance in the diagnosis of liver abscess.

3. **Tropical Liver Abscess.** Coffin reviews the statistics of the dysentery cases which occurred in Manila from Jan. 1, 1902, to Aug. 31, 1905. There were 1,523 cases, classified as follows: Amebic, 859; catarrhal, 236; dysentery, acute or chronic, 428. Only thirty-four cases were complicated by liver abscess. The history of three cases is given in detail; these patients were operated on, with a mortality of 33.3 per

cent. Coffin concludes as follows: 1. This condition should be known as hepatic amebiasis, the words "tropical" and "single" both being faulty in describing it; furthermore, it is not a true abscess as we understand the same. 2. The ameba coli, Lösch, is the exciting cause. 3. The routes of infection are the portal vein, over the peritoneum from the gut to the liver by amoeboid motion, and through the common bile duct. 4. The leucocyte count is comparatively high and always a valuable guide in the diagnosis.

4. **Cyst of Kidney Simulating Ovarian Cyst.**—Krusen reports a case of simple serous cyst of the right kidney, which from the diagnostic standpoint resembled a cyst of the right ovary with a long pedicle. The cyst was retroperitoneal, and on incision a quantity of clear, colorless fluid was evacuated. The walls of the cyst were very thin and tense and of a transparent bluish color. On examination it was found to be connected with the right kidney, which was considerably atrophied. No odor of urine was detected.

6. **Diphtheria Antitoxin Effective in Scarlatina.**—Lopez states that in his experience early curative doses of diphtheria antitoxin administered in scarlatina abort the disease, curtail suffering and lessen the risk to the patient, one dose of 2,000 units being sufficient in the average case of sore throat due to bacterial infection to effect a speedy cure. He also finds the serum equally effective in all anginas, be they scarlatina, tonsillitis, quinsy, etc., through neutralizing the toxins and reducing the fever and local congestion which contribute to the patient's suffering and the element of danger. There are no contraindications. Lopez says that it should be remembered that the largest quantities of serum the most severe cases may require, from 20,000 to 100,000 units, are not depressing to the heart, are not attended with any bad results or sequels and are without a single element of danger.

8. Etiology, Prognosis and Treatment of General Paralysis. J. Collins, New York.
9. *Therapeutic Value of Warm Moist Air and Hot Dry Air in the Treatment of Diseases of Children. T. W. Kilmer, New York.
10. *Pseudo-uremia of Childhood. W. H. Birchmore, New York.
11. *Mice and Pneumonia. E. Palmer, New York.
12. *Obstetric Methods Practised in the Philippines. W. D. Bell, U. S. A.
13. Care of the Sick outside of Institution. B. A. Rosenfeld, New York.
9. **Warm, Moist Air in Diseases of Children.** Kilmer advocates the use of warm, moist air in the treatment of children suffering from croup, acute bronchitis, asthma, pneumonia, diphtheria, laryngitis, whooping-cough, tonsillitis, nephritis, sprains and acute articular rheumatism. The apparatus employed by Kilmer consists of a tin funnel chimney; a firepot containing a Bunsen burner for gas and an alcohol lamp; a water boiler with a cover; a jointed tin tube in two sections with a gauze chamber, and an asbestos tube. It is impossible, says Kilmer, to upset this apparatus. It can be kept going for weeks, if necessary, with no attention save the occasional addition of water. The firepot may be turned upside down and the burner will not drop out. The apparatus may be carried from place to place while lighted, with no danger of setting fire to the house, scalding the patient or burning the hands. The method of using this apparatus for supplying warm vapor or hot, dry air is described in detail.

10. **Pseudo-Uremia of Childhood.** According to Birchmore, this disease is rare and its symptoms misleading. In those cases which came under his immediate notice the diagnosis of uremia had been made by skillful physicians. All the cases began with headache and chill in the older patients, with spasms and crying fits in the younger ones, followed by a sleep or lethargy sufficiently alarming to require the attendance of a physician. The skin was dusky or bluish in tinge. The pulse averaged 59, with a temperature of 102.4 and 103.2. In all the cases the pupils were much contracted. A hypodermic injection of sulphate of atropin to stimulate the respiratory center was at once given, and one of strophanthin, in preference to digitalis, to steady the heart. The breathing improved as soon as the atropin began to take effect. When

possible, an effervescing saline cathartic was given, the dose being repeated in half an hour, if necessary; this was followed in every case first by an evacuation of the bowels, and, secondly, by a disappearance of all the symptoms within ten hours. Birchmore is convinced that there are many other cases of indigestion or of faulty digestion in which the poison which overpowers the respiratory center is produced in sufficient quantity to do serious mischief.

11. Mice and Pneumonia.—From experimental evidence, Palier is convinced that the microbe causing pneumonia is very polymorphous, that a similar microbe is found in the mouths of healthy persons and that the microbes found in healthy individuals or in those suffering from pneumonia are not virulent enough to cause pneumonia when injected into animals like the rat, which is not very susceptible to them. On the other hand, these microbes acquire a great virulence when they are passed through a susceptible animal like the house mouse. Palier has named the bacteria in question *diplo-aeo-bacilli-coeri*, or, for the sake of brevity, *d. l. b. c.*, instead of pneumococci. He is furthermore convinced that the *d. l. b. c.*, which are found in the human being perform a useful physiologic function by preventing the invasion of other microbes and by acting as scavengers of the respiratory tract. For the *d. l. b. c.* to become virulent they must pass through a susceptible animal. Palier found that the house mouse is most susceptible to them, and hence has reached the conclusion that the house mouse is the main cause of pneumonia. Pneumonia is most prevalent in the months of December, January, February and March. At this time of the year there are usually many mice in houses, especially those in which the plumbing is defective and which are in a general insanitary condition. Young mice seem to be especially abundant in the month of March. They are also very susceptible to the *d. l. b. c.* These mice, either through their feces or after their death through their decomposing bodies, spread virulent *d. l. b. c.*, which may cause disease in man either by inhalation or by inoculation through an abraded surface.

12. Obstetrics in the Philippines.—Bell says that the belief that the women of semi-civilized races escape many of the pangs of childbirth is certainly erroneous regarding the Philippine natives. The life of the Filipino woman is comparatively short, due to her many pregnancies, much manual labor, insufficient food, and most of all to the crude, brutal and ignorant practices employed as obstetric aids. The two chief procedures used to facilitate expulsion of the fetus consist, first, in a stout band of cloth passed about the woman's abdomen and pulled tight by four persons, who are seated, two on each side of the patient, with their feet against her body; and, second, in a plank six or eight feet long by a foot wide, which is placed across the woman's abdomen, while another person, mounted on the plank, rises on his toes and lets the heels descend forcibly. The birth of the child is followed by the expulsion of the placenta by the above means, and, should the process be delayed, forcible traction on the umbilical cord is made to such an extent as to tear away portions of the placenta, and often large sections of this body are left to find their way from the uterine cavity of their own accord. Weeks and even months later the results of such practice are noticed in the septic conditions which would naturally follow retention of the membranes.

Boston Medical and Surgical Journal.

January 25.

11 *Development of Scientific Hydrotherapy. J. H. Pratt, Boston.
15 Description of Killian's Frontal Sinus Operation. E. E. Foster, New Bedford, Mass.

16 *Study of the Larynx in Tabes. D. C. Greene, Boston.
17 Etiology of Lateral Curvature of the Spine. M. Böhm, Boston.

14. Scientific Hydrotherapy.—Pratt declares that scientific hydrotherapy will not be used widely in private practice until it is taught accurately in the schools. In 1902 thirteen of the nineteen German universities gave special courses in physical therapeutics, many of which were devoted to hydrotherapy. In America, on the other hand, not one university gave a similar course. Pratt discusses the physiologic basis of hydrotherapy, the indications for its employ-

ment, and the results that may be expected from such employment. Six cases were cited which illustrate the beneficial results that sometimes may be obtained by hydrotherapeutics alone and combined with other remedial agencies.

16. Larynx in Tabes.—Greene reports the results of examinations made in 60 cases of tabes. These cases were observed with reference, (1) to the proportionate number affected with paralytic and other disturbances of the larynx; (2) to the nature of such disturbances; (3) to the period of their occurrence in the course of the disease. Out of the 60 cases examined, 9 or 15 per cent., presented laryngeal complications; 6, or 10 per cent., showed undoubted paralysis of one or both vocal cords; 7, or 12 per cent., were affected with laryngeal crises, three of these without evident paralysis of either cord, and one presented a jerky movement of the cord in moving from the median line. In regard to the nature of these disturbances, the only form of paralysis which Greene saw was abductor paralysis. Of the six cases, five were unilateral and one was bilateral. These were further divided into three with partial and three with complete abductor paralysis; that is to say, in the former there was marked limitation in the outward excursion of the cord and in the latter there was absolute fixation of the cord in the median position. With reference to the stage of the disease in which laryngeal manifestations appear, Greene found that laryngeal crises, when present, occurred among the earliest symptoms in all of his cases. In two the crises led to examination of the larynx and subsequent detection of the disease of the nervous system.

18. Perinephritic Abscess.—Of fifteen patients whose histories are reported by Guiteras, the source of the pus was traced to the kidney in fourteen. In one patient he thinks empyema was the cause. One patient at the time was in such a dangerous condition that a rapid incision was made without an anesthetic, and the man was too weak to permit of a careful examination of the abscess cavity, and after the operation he refused further interference. Therefore it is difficult to say whether the abscess in this case was of renal origin or not, but it presumably was, as the patient had a calculous cystitis and pyelonephritis at the time. In the other fourteen cases the kidney was involved. Guiteras thinks that many more cases of perinephritic abscess are due to suppurative renal disease than is generally supposed, a fact which will be proved with the rapid strides that are now being made in renal surgery. Traumatism, exposure and similar influences to which primary perinephritic abscess is attributed are often vaguely given as causes when they are simply coincidences of the active causes of rupture of already existing abscesses in the kidney or neighboring structures. Before the operation is done, pus should be looked for in the common urine and in the separate urine by the ureteral catheter. During the operation the surgeon should try to determine whether the kidney is the source of the pus, and, if not, what tissue or organ is. It is equally as important to discover the road taken by the pus, as it indicates where a counter-opening should be made and the further treatment of the case for complications. Guiteras sums up the elements of success in operations for perinephritic abscess as follows: (a) Early incision and evacuation before the pus has had time to burrow extensively. (b) Thorough exploration, without timidity, opening the kidney and exploring the ureter if need be. (c) Thorough drainage down to the deepest part of the sac by means of large soft rubber drains or gauze, the drain being kept in place until a

well-formed sinus exists down to the deepest part of the cavity. (d) Nephrotomy, nephrostomy or nephrectomy should be performed if indicated at the time of the operation or later.

20. Stool Examination in Starch-fed Children.—This study comprises the observations made by Kerley and Campbell on 57 children, 519 stool examinations having been made. Because of defective technic and errors in the early examinations, the findings in 27 children, comprising 353 examinations, are excluded. The report covers observations on 30 children, 166 examinations having been made. The stools were collected as follows: One-ounce tin ointment boxes, with the child's name pasted on the cover, were given the nurse in charge. A close watch was kept on the children, who were so grouped as to make this possible. As soon as an evacuation occurred a portion of the stool was placed in the tin box and sent to the laboratory. In order to make the test a severe one, raw barley flour was used, which was cooked one and one-half hours. In some cases barley water formed the milk diluent, in others it was given plain as the only nutriment. The method which they found the most reliable and which was used exclusively in the 30 cases was that known as the von Jaksch test. A considerable portion of the stool, a piece the size of a pea or larger, was placed in two drams of water, boiled and shaken, so as thoroughly to disintegrate the fecal particles. A few drops of Lugol's solution were then added and the solution was filtered and cooled. If starch was present, the characteristic blue color appeared. Filtration of the solution appeared to make but little difference as to the delicacy or reliability of the test. In the cases in which starch was not found, several portions of the stool were examined in order to make the examination a thorough one. In 16 children the examinations were persistently negative to starch. In five of these negative cases there was moderate diarrhea and in one severe diarrhea. The remaining eleven children showed sometimes positive, sometimes negative, sometimes red at the different examinations. Among the 30 children, 23 showed a good starch capacity. Of these, 11 had diarrhea, 7 showed poor starch capacity.

27. Management of Hospitals.—Ochsner discusses the functions and scope of the modern hospital and its successful management. So-called diagrams of authority are given for a large hospital, a hospital of moderate size, a small hospital and a medical staff, showing each person connected with the hospital, what his exact position is and who his superiors and subordinates are. With reference to the duration of service of the medical staff, Ochsner says that the plan of dividing the service into four active periods of six years each and then placing the physician on the consulting staff is probably the best. This includes six years of work as interne or two as interne and four as third assistant, six years as junior attending physician or second assistant, six years as first assistant or attending physician or surgeon and six years as chief of the department. After this the service would be in an advisory capacity, without any responsibility, for an indefinite period.

31. Tympanic Massage.—The technic of Beck's treatment is as follows: The mercury is heated over an alcohol flame for a time, so as to reach a temperature of 180° F. It is then allowed to cool off sufficiently, after which the tube containing the mercury is introduced into the external auditory canal. The heat is retained sufficiently long to give a treatment in one ear. The patient's head is inclined toward the side to be treated and the tube is fitted tightly into the ear, so that it closes like an otoscope. The tube is reheated to the temperature mentioned and is introduced into the opposite ear. A thorough examination of the tympanic membrane must be made before treatment is instituted, so far as perforations, cerumenal plugs and long hairs are concerned. After the treatment patients are somewhat sensitive as to the retention of some of the mercury, but by shaking the head slightly a little of the mercury will drop out. If some of it should remain in the ear no harm will be done. Beck has treated 261 patients by this method. Of this number not one experienced any bad or unpleasant effects. Universally the patients have declared that the noises in their ears have either disappeared or that they are very much improved. Of the patients that resisted this treatment, Beck was able to find some general condition more than the local ear trouble which was responsible for the tinnitus aurium, such as gastrointestinal or cardiovascular disturbances. In cases in which the condition was principally confined to the ear, the results were fairly successful.

35. Foreign Body in Maxillary Antrum.—On starting to clean out the antrum, Potts discovered some hard substance, the character of which could not be determined on account of the granulation tissue surrounding it. When grasped with a pair of forceps it was found to be loose, and a piece of hard-rubber pipette, measuring 4.5 cm. in length, was withdrawn. Ten years previously the patient had been smoking a pipe while riding horseback and was thrown. The tip of the pipe-stem he spat out of his mouth and the bowl was found; but, not being able to find the stem, he concluded that it had been knocked to some distance and lost. At the time of the accident there had been considerable bleeding into the mouth and some soreness, which symptoms disappeared entirely within a few days.

37. Foreign Body Removed from Bronchus.—Thirty hours before Elsborg saw his patient, a girl aged 4 years, she had swallowed a pin one and one-half inches long, with its head first. Immediately after she began to retch, vomited some bloody mucus and complained of pain and discomfort in the chest. After a few hours these symptoms disappeared and the child felt perfectly well again. She was kept on a fluid diet and the stools were watched for the pin, but none was found. The child had had no pain in swallowing or other symptoms. With the x-ray the pin could be plainly seen with its head downward in the fifth intercostal space, a little to the right of the median line. On the following day the patient developed signs of fluid in the right chest with signs of consolidation, high temperature and a rapid pulse. The presence of the pin in the esophagus having been excluded by the esophagoscope, it was more than probable that the pin lay in the trachea or right bronchus. Under chloroform anesthesia the bronchoscope was passed, but the foreign body could not be found. Elsborg then proceeded to do a rapid low tracheotomy, and passed a moderately-sized endoscopic tube through the tracheal opening and into the right bronchus. The shaft of the pin was grasped with slender forceps as far away from the head as possible, and the endoscopic tube then pushed down, the pin being firmly held by the forceps. By means of this procedure the point of the pin was freed from the wall and the shaft of the pin gradually bent into a full view, until the point was swept into the left bronchus. By repeating the procedure the pin was bent on itself, and, with the point and the head both pointing

downward, could be grasped at the angle and easily extracted. A tracheotomy tube was then inserted. The signs in the chest disappeared within two days, the temperature and pulse fell to normal, the tracheotomy tube was removed at the expiration of one week and the wound healed up rapidly.

38. **Elevator, Speculum and Forceps for Use in Submucous Resection.**—Hurd's elevator is a double-ended instrument, the sharp end resembling a Volkman curette, except that the cavity of the spoon is filled with metal, the other end made of copper, blunt and rounded. The flexibility of the copper allows this blunt end to be bent in any way desired. The speculum is to be used after the cartilage has been removed with a Ballenger swivel-knife. The long blade is passed between the membranes and the instrument is held with the left hand, with the long blade uppermost at all times. The down-cutting forceps is intended for use on the anterior nasal spine of the superior maxilla and on the vomer after the cartilage and bone have been removed from above. Hurd says that the advantages of this forceps are that no assistant is required; it will never injure the mucous membrane, as the chisel is liable to do; it keeps the parts well in view and secures a much smoother edge than that obtained by the chisel.

39. **A New Tonsil Tenaculum.**—The points of advantage claimed for this instrument by its originator, Bryant, are (a) simplicity of construction, (b) shortest possible time consumed in adjusting and releasing, (c) non-obscuring of field of vision, (d) leaving operator free to use both hands, (e) adaptation for right or left tonsil, (f) avoidance of injury to patient. The tenaculum is worked by a strong wheel-bearing spring, constant and uniform in action. The tonsil is held by three prongs, two of which seize it at the base, and the third comes in between the two at the apex, giving a secure hold, especially helpful in friable tonsils. The distal arms are locked beyond the range of the uvula and are separated on approximation by a steel block, thus preventing injury to that structure. Neither the wire nor canula of the tonsil-snare can interfere with the hinge of the tenaculum by slipping in between the arms at an inopportune moment. The horizontal convex curve of the shorter arms and the shape and size of the handles leave the line of vision and field of operation unobstructed, which is desirable in those operations requiring the use of the snare. The upper handle is shorter than the lower straight handle and terminates in an open curved projection, on which the thumb rests, assisting in guiding the instrument. The slightest pressure on the handles adjusts or releases the tenaculum. Its length is 21.5 cm.; weight, 113.40 grams.

40. **Surgical Treatment of Ptochus.**—The technique by which Thomson has obtained the best results is as follows: After making an incision through the skin following the upper border of the tarsal cartilage, and extending completely from one end of it to the other, the skin should be completely separated from the underlying orbicularis as low as the ciliary margin and as high as the orbital arch. This extensive dissection is necessary in order to give room and freedom for the subsequent steps of the operation. Two vertical incisions are then made through the orbicularis muscle, one on either side of the tendon of the levator, right down to the tarsal cartilage below and as deep as the conjunctiva above it. The portion of the orbicularis between these incisions, together with the tendon of the levator, is separated from the conjunctiva as far back as possible. When the dissection is carried upward about three-fifths of an inch, the cellular space between the orbicularis and the levator passes to the orbital margin, and the levator, where

it dips into the orbit, is readily found, and, working downward from here, the two planes of muscle are easily separated and the redundancy in the orbicularis is cut out. The tendon of the levator is then seized with a forceps to prevent it from slipping back into the orbit, and its attachment to the cartilage is cut. As much of the muscle as is deemed necessary is excised; this amount, of course, varies according to the degree of ptosis present. Ordinarily between 1½ and 3 mm. should be removed. Three mattress sutures are then inserted into the tendon, one in the center and one near each margin, and the other end of the stitches passed into the cartilage near its ciliary margin. Care is required to get the center stitch placed properly and the lateral sutures equally distant from it. The reason for using mattress sutures is to overcome any tendency the stitches may have to cut out. Silk is the best suture material. It is not necessary to bring the edges of the wound in the orbicularis together, because, owing to the shortening of the levator, they naturally fall in apposition. Thomson thinks it is well to remove a narrow strip of skin before bringing the cutaneous margins together, as otherwise there will be a fullness over the lid for some days. A dry dressing and a bandage are applied; the wound should be dressed daily. No disfigurement results from this operation.

41. **Pathogenesis of Spasmus Nutans.**—Schapring explains the appearance of unilateral nystagmus in spasmus nutans as follows: In early life it easily happens that one of two physically equal retinal images is not perceived and is disregarded by the mind, as is clearly shown in the typical strabismus convergens which appears in childhood. In those children in whom favorable internal and external conditions for the genesis of spasmus nutans are present, it often happens that the central perception apparatus, the mind, directs its attention on the retinal image of only one eye—for example, the left—and disregards that of the right. In consequence of this the impulses of labile eccentric fixation which go out from the center pass only to the left eye. In the age of life under consideration the law of equivalent motor innervation of the eyes does not possess its full force, and a unilateral nystagmus can appear, either in the form that only the left eye oscillates or that this eye oscillates more than the other. Therefore, when unilateral nystagmus accompanies spasmus nutans, the eye which oscillates alone or most perceptibly is to be considered as the "fixing eye," as that one whose retinal image is perceived and mentalized. In spasmus nutans, in addition to the nystagmus there occasionally appears a transitory strabismus, due to a spasm of a rectus or oblique muscle. This muscular spasm is to be regarded as a "confident movement" in no way contrary to the rule.

52. See abstract in THE JOURNAL, Oct. 28, 1905, page 1355.

54. **Tropical Splenomegaly.**—According to the authors, a clinical summary of this symptom complex, as it occurs in the Philippine Islands, shows that it is very closely related to, if not identical with, those forms occurring in other tropical countries, where it is variously known as kala-azar, dum-dum fever, etc. Young people from 15 to 25 years of age seem to be susceptible. The disease is almost invariably ushered in by an attack of remittent or intermittent fever, which clinically resembles malaria or dengue, and is accompanied by enlargement of the spleen. Recurrent exacerbations of fever at irregular intervals occur throughout the course of the disease. This fever is not influenced by quinine, and in the Philippines is recognized by the natives as a "cayama" or "quisig," and is held by them to be a disease distinct from malaria. The laity consider the disease a very fatal one and often of very short duration, but more often chronic, the patient living for several or many years. The spleen usually enlarges quite rapidly, reach-

ing its maximum size in the second or third attack of fever, and then very often no further change occurs, unless the idea of the natives that the organ grows harder is correct. The liver may or may not be enlarged, but when it is that change is secondary to the splenic enlargement. Jaundice, usually slight, but also well developed, is often present, sometimes even in those cases without enlargement of the liver. This fact accounts partly for the muddy, pigmented appearance of the skin and mucous membranes which is so commonly seen. There seems to be a special tendency to involvement of the mucous membranes in this disease. This is shown by the frequent gastrointestinal disturbances, conjunctivitis, etc. The natives say that this disease causes discharges from the vagina and sometimes also abortion. There is also a tendency to hemorrhages in both the mucous membranes and the skin. This tendency may be explained in some cases by the jaundice. Edemas, at first transient and later more marked and persistent, are common occurrences and are more common on the legs and face. Ascites and pulmonary congestion may also be marked. Anemia, emaciation and cachexia gradually develop in nearly all cases. Pain is a frequent but by no means a constant symptom. It is manifested by headache, arthralgia and myalgia, and apparently is more common in the early stages of the disease.

55. **Appendicitis.**—Morfit urges that every patient with an inflamed appendix should be operated on and the irritating or irritated appendix removed, even if not inflamed. There are times, he says, when operation might be deferred, but never abandoned, to advantage. The diagnosis should be made and operation decided on or not in the first six hours after seeing the patient. If twelve or twenty-four hours elapse after the onset of the attack the time of operation is open to discussion. Even in advanced stages, deferring operation to a more opportune time is so fraught with dangerous uncertainties as to make operative measures equally as promising as non-operative. Taking the cases as they come in all stages, the hundred operative cases will give a more flattering recovery and cure percentage than the hundred treated medically. Morfit claims that it is not faulty operative technic, but procrastinating diagnostic technic, that is responsible for most of the mortality.

60. **Treatment of Chronic Constipation.**—MacMillan experimented on dogs to observe the effects of different agents on peristalsis. To determine the effect of distention on the colon, the dog was anesthetized with chloroform and the abdominal viscera well exposed by long longitudinal and transverse incisions. The colon was immersed in normal saline solution at about 100 F. A collapsed thin-rubber bag was then inserted through the anus and made to rest in the rectum or colon. This bag had a tube attached for the purpose of inflation. By these means any degree of distention of the rectum or colon can be obtained readily. The presence of the uninflated bag in the bowel produced no contraction. Moderate distention was followed, after a length of time, varying in different dogs and in different parts of the bowel, by waves of contraction. Usually the contraction was seen to begin immediately above the bag, but occasionally it was first seen at some distance. As distention was increased the peristaltic contractions followed more rapidly, and wave after wave propelled the bag along. These contractions continued, even after the distention

had ruptured the bowel. In most cases strong contractions of the abdominal muscles accompanied the peristalsis when it had reached a certain strength. MacMillan concludes that these experiments demonstrate that distention of the bowel induces normal effective peristalsis.

66. **Simple Bandage for Fractured Clavicle.**—The bandage employed by Colomb is made from one piece of stout cloth, three yards long, for a child and from two and one-half to three inches wide. Enough of the bandage is folded over at one end to extend the full length of the forearm. This is sewed along the bottom, the lapel end and greater portion of the top, leaving an opening into which the band and arm can be passed easily. Once the arm is inside the sleeve, a safety-pin closes the opening more snugly around the arm, so as to prevent its removal. A few safety-pins where the folds cross make the bandage secure.

2. Enterospasm and Appendicitis.—Hawkins believes that there are patients whose symptoms are the same after as before an appendicectomy. The appendix being blamed unnecessarily for the existence of the condition for which the operation was performed. He is convinced that this condition is the result of enterospasm and cites a number of cases in support of his theory. The patient suffered from pain of a dull character, and often only from discomfort which becomes exceedingly intolerable after a spell of some weeks or months. The discomfort is relieved by satisfactory action of the bowels, but such an action is difficult to get, and strong, irritating purgatives aggravate it. The stools are commonly narrowed into pencils or ribbons. Pressure or massage will sometimes give relief in the slighter cases, and the hot bath may have a great effect. During the attack there is no desire to go to stool. There is a feeling of discomfort and tightness in the left iliac fossa, and the rectum is empty and thrown into folds, often with spasm of the sphincter. In the worst cases nausea is felt occasionally, but there is seldom any vomiting. In nearly all these cases some part of the colon, more commonly the descending portion, can be felt as a hard cord about the size of a man's forefinger. The bowel above the spastic part does not become dilated. No peristalsis is seen or felt, and the abdomen is seldom distended. Hawkins concludes that owing to the absence of all evidence of organic disease and the long duration of some of his cases, it is exceedingly unlikely that there is any structural change in the intestine or elsewhere, and that these patients are either neurotic or neurasthenic, the abdominal trouble varying directly with the mental state.

- 13 *Two Cases Illustrating Sciatica of Abdominal Origin; Laparotomy. F. W. Forbes-Ross.

8. Tuberculin in Tuberculosis.—Speaking of the accuracy of the opsonic index, Cheyne says that he believes that the result of the examination of the blood depends a good deal on the personal equation, and that it has not the strict mathematical accuracy that one could desire. Another difficulty is the cumbersomeness of the method which makes it impracticable for the busy physician. Cheyne has employed Wright's method in several cases of bone and joint tuberculosis and of genitourinary tuberculosis, but failed to obtain the expected satisfactory results. His view as regards the position of tuberculin in the treatment of tuberculosis is that it is a most valuable adjunct to the treatment now in vogue, but he is not prepared to abandon surgical measures when these are necessary. In circumstances in which no operation formerly or now would have been considered necessary, tuberculin should be used in conjunction with the other methods employed.

13. Sciatica of Abdominal Origin.—Forbes-Ross cites two cases in which the cause of the sciatica was only recognized when other subsequent, independent and direct symptoms drew attention to, and caused the sufferers to seek advice for, a condition of affairs existing within the abdominal cavity which had not hitherto been suspected as giving rise to the nervous affections. The first case was illustrative of what Forbes-Ross calls the true sensory physiologic reflex, nervous response

of one spinal segment to peripheral irritation existing in the area supplied by another adjacent spinal segment. The second case was a type of the usual pressure symptom case of pressure on both sciatic nerves caused by extensive adhesions of the pelvic organs. In the first case there was found a small, exceedingly tense, central cystic tumor of the left ovary about the size of a small orange. This tumor was removed and there has been no recurrence of the sciatica.

14 *Is Yaws Syphilis?* A. Castellani.

15 *A Simple and Cheap Rocker for Leishman or Other Stains.* P. N. Gerrard.

14. *Is Yaws Syphilis?*—Castellani reviews the clinical history of yaws and concludes that the symptoms, distribution and pathology of this affection show many points of difference from syphilis, and that the presence of a spirochete of the pallida type is not sufficient evidence to prove that yaws and syphilis are identical. He believes that though they may be closely allied, they are two different diseases.

19. *Action of Tea.*—According to Brunton, tea may interfere with nutrition in three ways: First, by lessening the feeling of hunger; second, by rendering food less digestible, and third, by interfering with the digestive power of the stomach. At the same time that it thus lessens the nutrition of the body it enables the person to use up much more energy than he or she would be able to do without its aid, and the consequences of this are most evident in the effect on the nervous system. Although tea prevents the sensation of fatigue from being felt for a while, yet exhaustion is going on, both in mind and body, and this usually at length causes disinclination to either mental or bodily exertion, and tends to destroy the power of doing any useful work, either mental or physical, even when the attempt is made. Power of self-restraint is diminished and the person becomes nervous, unduly sensitive, timid and emotional. Not infrequently ringing in the ears is felt, giddiness, headache, sometimes very severe neuralgia and tremulousness. The tremors seem to be more readily induced by green tea than by black tea, and Brunton has known of one case in which two or three cups of green tea were sufficient to induce marked tremor. Neuralgia is very apt to occur in nervous people who are able ordinarily to take a great deal out of themselves, either by sheer force of will or under excitement, and are thus more liable to reduce themselves below normal than those of more lymphatic temperament. Neuralgia has been described as the prayer of a nerve for better blood and more of it, and tea, by enabling these people to take even more out of themselves than they otherwise could, will render their neuralgia more severe and more continuous. It is evident that a similar result is to be expected in regard to other nervous functions, and that the stability of the brain may be so seriously impaired that the combination of starvation and stimulation, produced by excessive tea drinking, will certainly produce a tendency to mental derangement, even if it does not actually determine its onset. In addition to its action on the nervous system, however, tea is a powerful stimulant to the circulation, and, if abused, will lead to feebleness of the pulse and to palpitation. All teas are not equally injurious. Ceylon and Indian tea are preferred by many people to China tea on account of their aroma and stimulating qualities, and, so long as they are taken in moderation and prepared in the right way by simply infusing for two or three minutes, and then pouring the water off from the leaves, they will suit healthy people very well. Whether on account of the higher proportion of tannin they contain, or some other reason which we do not yet know, they are not so good for weak digestions as China tea, which, especially if it is prepared in the way just recommended, by infusion for two or three minutes only, is less

likely to cause dyspepsia than other kinds of tea. The physiologic action of tea is usually attributed almost entirely to the alkaloid, theine or caffeine, which it contains, but Brunton does not think that this can be the case because green tea, which contains no more of the alkaloid than black tea, has a much more powerful effect on the nervous system, an effect which can not be explained by the somewhat larger proportion of tannin, and must, he thinks, be due to some other constituents in the leaf. Green tea and black tea are not obtained, as many people suppose, from different varieties of the plant, but only differ in their method of preparation; the leaves which form the green tea being roasted in a pan shortly after they are plucked, while those that form the black tea are allowed to undergo a form of fermentation before roasting. Brunton sums up his paper as follows: Tea when properly prepared, and taken in moderation, is both useful and agreeable. When taken in too great quantity, or along with meat, when too strong when infused too long, or still more when boiled or stewed, it is apt to produce digestive troubles. When taken in excess it may produce nervous symptoms of the most serious character, and facilitate, if it does not actually produce, mental degeneration.

Bulletin de l'Acad. de Médecine, Paris.

24 (Year LXX, No. 1.) **Etude du tetanos dit médical ou spontané. Influence de la chaleur (of heat).* Vincent.

24. *Atmospheric Influences in Tetanus.*—Vincent announced in 1891 that the microbe of tetanus does not flourish in the living organism unless it encounters special conditions which favor its proliferation, such as the action of chemical or microbial toxins, mechanical changes in the tissues, hemorrhage, etc. He now announces that exposure to heat is one of the most potent influences that can favor the proliferation of the germs of tetanus. A young man succumbed to acute tetanus, but nothing could be discovered to explain the origin of the infection. There were no bruises or history of any accident. It was learned, however, that about a week before the first symptoms the young man had suffered a heat stroke after prolonged exposure to the sun. Vincent assumed that this heating of the body had been the condition which enabled the tetanus germs to proliferate, and experiments with animals confirmed this view. Guinea-pigs injected with a small amount of tetanus cultures did not exhibit any symptoms unless the animals were placed in the incubator at a temperature of 104 F. They were removed from the incubator when their temperature reached 107. In a few hours the temperature had returned to normal, but two or three days later, while the controls were and remained healthy, the animals which had been subjected to heat developed symptoms of tetanus and died with symptoms suggesting tetanus affecting principally the viscera. The exposure to heat was followed by the development of tetanus, even when an interval of from thirty to sixty days had elapsed after the infection and before the exposure. The virulence of the germs could not have been enhanced by the comparatively low temperature of 104. The results observed must have been due to the lowering of the resisting powers by the action of the heat. To confirm this theory he exposed to the heat a number of normal guinea-pigs and studied the effect of the exposures on the leucocytes. As soon as the temperature rose to 107 pronounced leucocytosis was always observed, affecting principally the cells most actively engaged in phagocytosis. The changes observed in the phagocytes readily explain the lowered resisting power of the organism and the way in which the tetanus germs proliferate unmolested. The germs multiply rapidly and spread throughout the organism, inducing fulminating symptoms of splanchnic tetanus. The germs may remain absolutely latent and quiescent in the system until allowed to proliferate by the lowering of the resisting powers. The period of incubation in such a case dates only from the moment when the germs began to develop unchecked, not from the time when the germs gained entrance to the body. In discussing Vincent's paper Kelsch remarked that the idea that exposure to heat is able to favor the proliferation of germs in the body may possibly explain why typhoid, dysentery, etc., are more severe in the tropics, and also why France suffers more from typhoid fever than the countries of Europe farther north.

Semaine Médicale, Paris.

25. (XXVI, No. 1.) *Spirilles, spirochetes, et autres micro-organismes à corps spiralé. R. Blanchard.

26. Micro-organisms with Spirally Twisted Bodies.—Blanchard's article is a historical sketch and description of the various forms of spirobacteria and of the trypanosomidae. The spirobacteria include the genus spirosona, the genus vibrio and also the spirobacillus and the spirillum. He describes about two dozen varieties of the latter. The trypanosomidae include the genus spirochata, of which he describes twenty-one species; the Schaudinn genus trypomona (hitherto called the *Spirocheta pallida* of syphilis), the genus trypanosoma and the genus trypanoplasma. Comparative study of these various micro-organisms shows the vast differences between the spirobacteria and the protozoan trypanosomidae, and also shows how members of both groups are able to adapt themselves to the special conditions of life as a parasite. It shows also the degrees of virulence and the varied roles they play in human and comparative pathology, and points the way to new fields of research in the field of parasitology.

29. Comparison of the Clinical and Pathologic Anatomic Findings in Cancer.—Pankow found cancerous glands in 38.2 per cent. of the cancer material at his disposal, which included three corpus and sixty-seven cervix carcinomas, all just removed. The uterus was involved in only one case, and then to a very slight extent. It seems able to resist cancerous encroachment. The bladder is also quite resistant. His findings compel him to advocate the necessity for extensive resection of the parametrium in ablation of uterine cancer. The abdominal route is the only one to be considered in such cases. The surgeon should not hesitate, Parker says, to implant both ureters in the bladder, if necessary. In three such cases, with impending uremia, great benefit was derived from resection and implantation of both ureters in the bladder.

39. Injuries of the Diaphragm. Suter reports the operative cure of two patients with severe injury of the diaphragm, one requiring also nephrectomy. He has found records of sixty-one cases of stab wounds of the diaphragm in which an operation was attempted and four of bullet wounds. More than 72 per cent. of the patients were treated by a trans-plenal operation, with permanent or temporary resection of ribs, the mortality being only 5.6 per cent. The mortality in the twelve cases requiring laparotomy was more than 53 per cent., while it was 25 per cent. in the cases complicated by injury of other organs.

40. Intramesenteric Ileus. Zade applies this term to the obstruction from constriction from acute dilatation of the stomach and to chronic dilatation. More or less complete

mesenteric ileus is liable to follow this combination, possibly favored further by relaxation of the abdominal walls or by unusual length of the mesentery.

34. Surgery of the Thoracic Part of the Esophagus.—At the Breslau clinic a special study has been made of the thorax and of the possibilities of surgical intervention since the invention of Sauerbruch's air-chamber for operating under minus pressure. Fourteen patients have been operated on by this technique and the results fully confirm its feasibility. These operations show that the thorax can be opened wide in the air-chamber without disturbing the respiration or heart action, and further that the esophagus can be amply exposed by a transpleural intercostal incision. This incision allows sufficient oversight of the organ for adequate surgical intervention.

37. Principles for Treatment of Peritonitis.—Nützel concludes from experiences at Frankfurt that the benefits of operative treatment of peritonitis are due to the removal of pus and of the cause of the suppuration and the drainage of abscesses and recesses, while it stimulates the peritoneum to increased resistance. The peritoneum owes its resisting power to its destruction and digestion of bacteria and absorption of the products of inflammation. Opium robs the peritoneum of its resisting powers by holding it immovable and thus preventing the distribution of the infectious material over a large surface. Delay should not be considered when peritonitis is once diagnosed, only excepting the irritation of the peritoneum which accompanies gonorrheal affections of the tubes and certain puerperal affections of the uterus and adnexa. Spontaneous recovery from severe peritonitis is extremely rare. Nützel believes in copious rinsing of the peritoneum, with ample drainage and counterdrainage. In his hospital a jar holding 150 liters of saline solution, on the floor above, is used to flush the field of operation. The tube and drain are sterilized by steam under pressure through them before they are used. The promotion and maintenance of peristalsis are the chief aims of the after-treatment, and twelve drops of physostigmin salicylate (.02 to .20), by mouth, is preferred by him to subcutaneous use of drugs. From 1,500 to 2,000 c.c. of artificial serum are injected at once after the operation. In the after-treatment anæsthetics are advocated. Absolute repose should be strictly enforced.

39. **Infrasympphysis Drainage.**—Hannes relates the particulars of three cases in which the bladder was drained through a tube introduced between the urethra and clitoris after a plastic operation on the urethra. This allowed the urethra to heal undisturbed by irritation from urine or from a catheter introduced into the bladder through the urethra. The bladder was partly filled first with about 100 cc. of sterile water to determine the permeability of the new-formed urethra. Then an ordinary trocar, about 5 mm. in diameter, was inserted through a small incision in the mucosa about 2 cm. from the opening of the urethra and easily pushed through into the bladder. The trocar needle was drawn out, but the cannula of the trocar was left to serve as a permanent drain. The small hole made by it closed up at once when the cannula was finally withdrawn.

42. **Puerperal Self-Infection.**—Abtfield cites a recent article by Natwig to sustain his assertions that streptococci are found almost regularly in the vaginas of healthy women and that the conditions of child-birth favor the acquisition of pathogenic properties by otherwise harmless saprophytes in these parts. There is always a liability that some of these germs may find their way into the internal genitals and induce self-infection.

49. **Congestive Hyperemia in Gynecology.**—Eversmann reports experiences with local suction applied to the uterus. His apparatus is a glass speculum shaped like a test-tube with a small branching tube near the rounding bottom. A rubber tube connected with this small branching tube has a stop-cock and terminates in the suction pump. The open end of the speculum is applied to the os uteri and a vacuum is produced with the suction pump. The os is sucked far into the speculum and can be seen to be very much congested. He applies this congestive hyperemia for a twofold purpose: to remove the secretions and to stimulate the circulation in the uterus. His experience has been eminently favorable, especially in cases of endometritis with considerable discharge. He applies the suction for half an hour at a time, with intervals of several days, gradually shortening the intervals until the applications are made daily. After five minutes of suction the stop-cock is opened for a full minute. Suction is then applied again, this alternation of suction and normal atmospheric pressure being one of the factors in the treatment. Tough and painful cords in the Douglas pouch also gradually softened and were absorbed in the course of this treatment, possibly owing to the better conditions of the circulation in the parts or to massage from the alternating drawing outward and retraction of the os uteri. He has had no experience yet in the application of this treatment to amenorrhea or as a preliminary to dilatation of the os uteri before artificial delivery. In slight lymphangitis of the breast the results of this congestive hyperemia were remarkably successful, as also in cases of insufficient milk secretion. When the suction apparatus was applied in this alternating technic for thirty minutes twice a day, the previously small amount of milk soon became ample for nourishing the child.

50. **Is Syphilis a More Serious Disease Than Gonorrhea?**—Doktor points out that gonorrhea may cause fatal affections, although the primary gonorrheal cause may have been long forgotten. He cites a number of instances of fatal retention from stricture, prostatitis, nephritis, etc., the result of gonorrhea. He also relates a number of cases of constant illness on the part of the wife, recurring inflammation, weakness, sterility, etc., destructive of all happiness in the home. Syphilis is less insidious and its ravages are confined more to the unmarried and to males, while the ravages of gonorrhea are felt more in the family and by the wives. Both should rank as extremely and equally serious diseases.

58. **Treatment of Total Prolapse of the Uterus.**—Holst's method consists in supravaginal amputation of the uterus, with subperitoneal care of the stump, concluding with fixation of the stump to the abdominal wall. It is applicable only to women near the menopause, but promises well in such cases. As the cervix, not the fundus, is fastened to the abdominal

wall, the walls of the vagina are held up and there is no secondary prolapse of the vagina.

60. **Toxic Action of Camphor.** Happpen reports the death after injection of camphor in an eclamptic patient, and discusses the limits of the therapeutic dosage. Part of the camphor enters into a harmless combination with glycuronic acid in the body and part is exhaled through the lungs. The fraction remaining is what exerts the therapeutic action on the vascular system. He concludes from his research that the fatal dose is about 1 gm. to the pound of body weight of a healthy human being or animal. The toxic dose is a third less. These proportions are less in persons who at the moment of the injection are not able to form or have not already on hand the amount of glycuronic acid necessary to combine with the camphor to form the harmless campho-glycuronic compound. As glycuronic acid is a product of the oxidation of grape sugar, when there is a lack of either grape sugar or of oxygen there will be correspondingly less glycuronic acid, and in such case a smaller proportion of camphor will have a toxic action. This assumption was confirmed by his experiences with twenty out of thirty-five rabbits on which he experimented. Healthy rabbits bore intravenous injection of .08 gm. of camphor without apparent injury, but this amount proved rapidly fatal if they had been fasting, and thus deprived of grape sugar, from six to nine days previously. Similar experiments in which the animals were deprived of oxygen, instead of the grape sugar, proved equally fatal when the camphor was injected, the animals succumbing after injection of .02 or .04 gm. of camphor, from one-fourth to one-half the previously tolerated dose. These findings were corroborated by the effect of glycuronic acid injected at the same time with the camphor. Animals thus injected showed little, if any, disturbances and were soon as lively as ever, while the controls all died. These experiences warn physicians to be cautious in administering camphor to patients whose carbohydrate metabolism is defective, such as cachectic persons or those in inanition, or in severe cases of diabetes or chloral poisoning. On the other hand, great caution is necessary in administering camphor to persons with a deficient supply of oxygen, as in carbon dioxide intoxication, in severe cardiac defects, in advanced bilateral pneumonia, in severe sepsis and to eclamptics. In case of eclampsia and states of psychic excitement, camphor is further contraindicated on account of the fact that its base of action is in the central nervous system.

63. **Pathogenesis of Tetanus.**—Zupnik's researches have demonstrated, he thinks, that the tetanus virus acts in two ways: it increases reflex excitability on one hand, and on the other it causes rigidity in the muscles. The virus acts on the muscular system and on the spinal cord. It affects the latter like strychnin, but in the muscles it induces solely rigidity. Both the muscles and the spinal cord receive the virus by way of the blood alone. The practical consequences of these assumptions, which he sustains by the results of experimental research and of clinical experience, are that it is useless to inject antitoxin into the nerves, spinal cord, subarachnoid space or brain, as the virus circulating in the blood can be reached just as well by a subcutaneous injection. Narcotics and the prophylactic avoidance of reflex excitations are the basis of treatment of the increased reflex excitability, but we have still to seek for a remedy that will conquer the permanent rigidity of the muscles.

65. **Surgical Treatment of Puerperal Pyemia.** Opitz relates a case in which he followed Baum's technic and ligated the efferent veins as the last resort in puerperal pyemia. The

patient died, but an uncompensated heart affection was chiefly responsible for the fatality. This brings to nineteen the number of cases of puerperal pyemia in which operative treatment was attempted, with six recoveries. In his experience with this affection Opitz has witnessed thirteen recoveries in eighteen cases treated by medical measures alone. Recovery is, therefore, possible without an operation. Nevertheless he regards surgical treatment as a great advantage, only he urges that it should be applied with discrimination.

67. **Vibrating Chair as Preventive of Seasickness.**—Peters describes an electric chair which is being tested on ocean steamers as a preventive of seasickness. The seat of the chair is in constant motion, resembling the jolting of an automobile. This prevents the perception of the motion of the boat, it is claimed. His experience has been rather encouraging with it, although he suggests certain modifications.

72. **Postmortem Study of Tuberculosis in Children.**—This communication from Escherich's clinic at Vienna reports the findings of the prosector, Ghon, in 401 autopsies of children. Of this total, 160, or 40 per cent., were found affected with tuberculosis. Death was due to the tuberculosis in 100 per cent. of the young infants, in 68 per cent. of the children up to 2 years old, in 65 per cent. of the children up to 5 and in 17 per cent. of the children between 10 and 14. The tuberculosis was found active in 40 out of the total 160, inactive in 10 and healed in 27. No signs of healed lesions were found in any children under 3, but the proportion increased progressively with this age upward to 47 per cent. of the 17 children between 10 and 14. The findings confirm those of Naegeli and others in regard to the increasing frequency of tuberculosis as the individual increases in years, with a corresponding decrease in the mortality of the tuberculosis. Fully 60 per cent. of the children who died from tuberculosis succumbed to tuberculous meningitis, but in 64 out of 67 such cases the meningitis was secondary to tuberculous of some other organ, subacute or acute general tuberculosis. In only 27 per cent. of the entire 110 cases in which death had been due directly to the tuberculosis were the lesions those generally observed in adults; all the others were those of tuberculous meningitis (60 per cent.) and milary tuberculosis. The mesenteric glands were found affected in only four instances. There were no indications of primary intestinal tuberculosis in any case. The article compares the findings recorded with those of Naegeli and other investigators, the concordance in the results being striking.

76. **Post-scarlatinal Lymphadenitis.** Schick describes the glandular affection which frequently appears in the third or fourth week after the first symptoms of scarlet fever. The glands involved are in the submaxillary region, and their in-

flammation and tumefaction are the most frequent cause for the recrudescence of fever during convalescence. This lymphadenitis enables a retrospective diagnosis of scarlet fever. The treatment found most effectual was cold applications at first, with hot applications later if the affection progresses, and incision in case of fluctuation. The general health does not seem much affected, frequently in marked contrast to the high fever. In a few cases the child seemed sick, the symptoms suggesting, to a certain extent, those of scarlatinal nephritis. He has observed seventy-one cases of the lymphadenitis in 990 patients with scarlet fever during the years 1902-1905. Usually but one of the submaxillary glands is affected.

81. **Sudden Death in Course of Eczema.**—Bernheim-Karrer discusses the mystery of the sudden deaths of children with eczema of the scalp and face. In one such case the autopsy revealed an unsuspected streptococcus focus in one lung, the action at a distance of these germs having induced slight endocarditis and pleural effusion. In another case an infant with eczema exhibited attacks of heart weakness, possibly from a similar action of the germs on the heart muscle. Another child of eleven months was in his care for recurring eczema of the scalp and face. The child was brought to him, after two months' absence, on account of a new patch on the cheek, and he was impressed with the dull look in the eyes, but nothing abnormal could be detected in lungs or heart. The cervical glands were swollen. He ordered a salve of ieththyl and zinc oxid. The child seemed unusually quiet and was found dead the second morning. Staphylococci were discovered in the cutaneous lesions and in the internal organs. Their numbers were not large, but it is possible that the eczema may have generated toxins, similarly to extensive burns, which may have induced an actual toxic form of staphylococcus mycosis. This assumption was confirmed by a number of experiments on animals. Infection with the staphylococcus alone did not cause by any means such severe symptoms as when the staphylococcus infection was supplemented by a cutaneous lesion, such as a croton-oil blister. The heart seemed to suffer particularly in these cases. The researches reported emphasize the importance of careful oversight of the heart action in cases of extensive eczema. Possibly the blood pressure might afford useful information.

84. **The "Tetany Face."**—Uffenheimer gives several illustrations of children to show the peculiar expression characteristic of tetany. It may be observed even before any other signs are manifest. The muscles of the face feel the influence of the impending tetany and the face assumes an expression which is the first faint suggestion of the *risus sardonius* of true tetany. He has observed more than fifty cases, his attention being attracted to the children by this tetany face, the application of electric tests or later events confirming his diagnosis. Differentiation at this early stage allowed prompt treatment and cured many of the children without the outbreak of actual tetany. The Chvostek and Trousseau signs subsiding as the children's expression returned to normal. The muscles affected are those innervated by the facial nerve; the face is drawn up and wrinkled like that of a harassed adult, worried and morose.

96 *Congestive Hyperemia in Treatment of Inflammatory Affections of Head and Face.—*Behandlung entzündlicher Erkrankungen von Kopf und Gesicht mit Stauungshyperämie.* W. Keppler. (Continued in No. 45.)

86. Torsion of Tumor in Omentum.—Riedel has encountered six cases of tumor in the omentum complicated by torsion, and thinks that this condition is not so rare as generally supposed. Four of the patients were operated on for assumed appendicitis. In two patients the twisted portion of omentum was in a hernia. In describing the details of these cases and discussing the removal of the tumors after ligation of the pedicle he emphasizes the importance of using catgut—never a foreign material like silk. This is especially important in case of the omentum, as its tissue is exceptionally liable to react with a serous inflammation to the slightest injury. It generally subsides spontaneously, but in case of the presence of a foreign material like silk there is liable to be prolonged and serious trouble. He has had some experiences of this kind, as he relates in detail.

87. Ants as Carriers of Typhoid.—Mayer describes an experience with some laboratory mice which indicates that ants may carry typhoid infection. Ants had access to the cages of some mice infected with mouse typhoid bacilli, and also to some other cages of sound animals. Soon after the presence of the ants was noticed, all the sound animals sickened with an epidemic of mouse typhoid. Plates of culture media over which the ants were allowed to run developed colonies of the mouse typhoid bacilli in a single straight line along the course of the ants, showing that the bacilli must have been retained as bees hold honey material, or else must have been passed in their dejecta. The colonies of other micro-organisms that developed on the plates were in parallel rows, corresponding to the ants' legs. Soon after these experiences Mayer himself developed an acute, brief but quite severe illness from infection with the mouse typhoid bacilli. The latter were found in his stools and urine, and the agglutination test was positive for the mouse typhoid bacilli at 1/250 during the second week. Severe pains in the epigastrium were a prominent feature of the illness, with diarrhea, chills, slight temperature and great depression. He was able to be up and about in five days, but the pains did not entirely subside until the sixth week.

89. Elimination of Uric Acid in Gout.—Eschenburg had occasion to make a prolonged and careful study of the metabolism in two gouty patients—an opportunity which seldom happens, as patients in the gouty category are generally unwilling to submit to prolonged research of this kind. The particulars learned are arranged for comparison with the findings in a healthy control subject. They show that the elimination of uric acid is quite irregular. Alcohol seems to increase its elimination in young persons, but does not have this effect in older subjects.

90. Self-Purification of Water.—Hofer has been making an extensive study of local conditions and announces in consequence that the self-purification of water is a biologic process, depending on the weeds and micro-organisms in the water. A rapidly-flowing stream does not purify itself so readily as a more sluggish stream with a more abundant flora. Where the river at Munich has been walled in and its channel narrowed it does not purify itself, but where it spreads out on a natural-soil bed and weeds accumulate the water soon becomes purified. He advocates draining organic matters into simple natural ponds. Instead of emptying the bottoms of these tanks the natural-soil bottom should be left and as large a surface provided as possible. The ponds should be stocked with appropriate plants and fish, and the waters will spontaneously purify themselves without putrefaction of the organic matters. He cites instances where this has been successfully accomplished for isolated establishments or villages. In one the waters from a factory contained 198 mg. of sugar to the liter, and 100 cm. of such water flowed daily into a pond covering 800 square meters, this residual water being diluted with twice the amount of pure spring water. The sugar was completely destroyed and the nitrogen dropped from 9 to 5 mg. The supply of spring water was cut off after a time and the normal biologic process was thus suspended. The pool is now scarcely more than a cesspool. The fish that can be

raised in a pond where the biologic process of self-purification is going on properly might prove a source of revenue.

91. Medicolegal Aspect of Case of Veronal Poisoning.—Harnack discusses a recent sensational case, in which a physician prescribed for tapeworm 5.5 gm. extract of male fern in capsules with 10 gm. (155 grains) of kamala as the "box powder." The patient took the entire contents of the box and died soon after. Chemical tests indicated veronal poisoning, and it was assumed that the druggist had used veronal instead of the kamala ordered. Harnack's testimony is to the effect that the intoxication was the result of the combination of the action of the male fern and of the drug veronal.

96. Congestive Hyperemia in Treatment of Inflammatory Affections of Head and Face.—This article issues from Bier's clinic at Bonn and gives the details of the successful application to the head and face of his method of inducing therapeutic congestion by constriction. The anatomic conditions, it states, are peculiarly favorable for this treatment in the head and face, as the blood vessels are so numerous and the blood supply so ample that even very slight constriction of the neck will produce the congestive hyperemia desired. This revolutionary treatment of inflammatory conditions has proved especially effective in inflammatory affections of the eyes, ears, nose and accessory cavities. The subjective disturbances were always relieved more or less, the subsidence of the pain being so marked that the patients soon clamored for the "neck garter." As the clinic is surgical, the material was not very well adapted for such therapeutic research, the patients being all in such advanced stages of the disease that they had been referred to the surgeon. The results observed, Keppler remarks, should encourage extensive trials of the technique by ophthalmologists, otologists and practitioners generally, and he is sure that it will soon win friends. He relates the details of a number of cases of acute mastoiditis favorably influenced by this treatment. The results were fully as good, if not better, than from extensive surgical intervention. The affection heals without necrosis of the bone, the same as in osteomyelitis of the long bones treated with the congestive hyperemia in the same way. One patient with suppurative meningitis was also treated; the pain was arrested at once, followed by the rapid retrogression of the objective symptoms. Similarly favorable results were obtained in the single case of extremely severe chorea treated. In some cases of secondary parotitis recovery proceeded rapidly under this treatment and all complications were averted. There has been no opportunity in the clinic to observe the effect of this procedure in primary parotitis. In one case of acute dacryocystitis this treatment alone proved promptly effective; in a second case an incision was made into the process. The cure was strikingly prompt in both cases. Large abscesses in the jaws also healed rapidly under the congestive hyperemia. The constricting band used is of cotton elastic, a little over an inch wide (3 cm. for adults and 2 cm. for children). It is finished with a hook in one end and a series of eyelets close together in the other, so that the band can be hooked tighter or looser. A single layer of muslin inside prevents chafing. The band is hooked at the back, and at this point has a small square of felt to protect the skin from hook and eyelets. The skin can be loosened by being washed with alcohol every day. Children have worn the constricting band for weeks in some cases, but no unpleasant by-effects were ever noted, not even in arteriosclerotic patients. The elastic must be replaced every few days, as it soon deteriorates from the moisture of the skin. The constriction should cause the face to look slightly bluish-red and somewhat bloated; the inflamed part usually shows a localized red fiery edema. The constriction is applied for from twenty to twenty-two hours a day. A remarkable evidence of its efficacy is that the pains are liable to recur as soon as the band is removed. The principle followed was to open an outlet for the secretions, if possible, with a very small incision, and then to apply the constricting band. An incision much smaller than under other circumstances answers the purpose, the congestive hyperemia completing the task. The process heals without the destruction of the bone and soft parts, which has hitherto been supposed inevitable. The incision is made at once, without waiting for fluctuation, and the

abscess or other inflammatory affection is aborted or rapidly heals. The ideal for therapeutic congestive hyperemia, however, is to apply it at the very first indications of trouble.

99. Streptococci in the Lochia of Normal Parturients.—Schenk and Schell report that about a third of normal parturients harbor pathogenic streptococci in the lochia, virulent for mice and rabbits. They examined 100 normal parturients and found positive results in a third from the seventh to the ninth day. Before this time the discharge is almost always sterile—that is, as late as the fifth day. They review the articles that have previously appeared on the subject and discuss the reasons why the streptococci do not cause trouble in these cases, without coming to any definite conclusion.

101. Spontaneous Cure of Chorioepithelioma.—In one of the two cases described, the microscope revealed the elements of a chorioepithelioma in the scrapings of the uterus. A mole had been diagnosed and masses removed from the uterus on several occasions. Recurring hemorrhages finally proved fatal. Velits believes that if the entire uterus had been removed early the patient might have been saved. She was a xvi-para, with a history of three abortions. The second patient was a younger woman, a v-para, with two abortions. The diagnosis of a mole was confirmed by removal of necrotic masses from the uterus. The symptoms were very severe, but the microscope failed to reveal any evidences of chorioepithelioma, and before long the patient had entirely recovered. The microscope is the test for malignancy in these cases.

103. Spontaneous Injury of Vagina During Delivery.—Sitzenfrey reports a case in which the spontaneous delivery of a rather small child caused, under his eyes, a rupture of the vagina, of the floor of the pelvis and of the perineum. Notwithstanding all his efforts at hemostasis, the hemorrhage was so severe that the patient succumbed.

104. Cancer in Abdominal Wall After Removal of Benign Ovarian Tumors.—Polano has had a case of this kind, of which he relates the details, with illustrations. He has found records or seven similar cases in the literature. He admits four explanations of the phenomenon. The general assumption at present is that the benign tumor cells transplanted into the abdominal wound undergo cancerous degeneration in the new culture medium. There is also always a possibility that the ovarian tumor may have been malignant; also that an ignored cancer in the stomach, intestine, uterus or elsewhere may induce a metastatic tumor in the abdominal cicatrix. The only other plausible explanation is that the cancer may originate primarily in the abdominal cicatrix.

Books Received

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merit, or in the interests of our readers.

Address

THE ESSENTIALS OF SUCCESSFUL PUBLIC HEALTH ADMINISTRATION.*

A. C. ABBOTT, M.D.
Chief of the Bureau of Health,
PHILADELPHIA.

At the present time nothing can be more appropriate than a discussion of certain modern views concerning public health administration and the auxiliary factors that go to make such administration a success. While the problem of public preventive medicine would, *a priori*, seem to be easily soluble through the employment of well-established principles, it is found by actual experience to be beset with difficulties, many of which would not exist were there a more intimate acquaintance, on the part of all concerned, with the requirements of the work.

PLEA FOR PROFESSIONAL CO-OPERATION.

With an audience of this character it is perfectly warrantable to assume that success in public health work is not only desirable, but actually demanded, and to expect, therefore, from each individual such co-operation as lies within his power to give. Proceeding on that assumption, it is my purpose to indicate in the course of these remarks the manner in which I believe this demand may best be met.

It is an unfortunate fact that many physicians, as well as laymen, regard the problem of public preventive medicine as soluble through the inscription on the statute books of specific laws, and the appointment of boards whose duties it shall be to see that such statutory regulations are enforced. As a matter of fact, such a combination represents only the nucleus about which are assembled the various accessories that together constitute the machinery which, according to the perfection of its organization and the smoothness of its running, promises success or failure to the undertaking.

You have only to reflect for a moment on the objects and aims of public health organizations to realize the impossibility of progress when the hands of those responsible for administration are tied by inflexible laws on specific topics, and when the only assistance available for the correct conduct of the work is that officially supplied. You have only to consider the manifold ramifications of the problem to realize how impossible it would be for any community to secure and support a corps capable of collecting all the data essential to a full understanding of prevailing conditions. Yet the collection of such data is of fundamental importance to the accurate performance of the duties for which the authorities are held responsible. In what manner, then, is the deficiency met? It is met by pressing into service those

of the community who, by virtue of their calling, possess the knowledge needed by the authorities, i. e., by requesting the medical profession to co-operate to the extent of prompt notification of all matters bearing on the public health that come to their notice in the course of the day's work.

It may never have occurred to you that, as practitioners of medicine, you are in affiliation with a department of health. It is true your names do not appear on the list of municipal employes, and there are no monetary compensations reaching you at fixed periods as agreeable reminders, but you are, nevertheless, a part—a most important part—of that branch of the administration, and have been so since the date of your registration as practitioners in this commonwealth. In evidence thereof you have supplied to the authorities information of vital importance to the detection and isolation of dangerous diseases; you have given to them substantial support in efforts to enforce regulations aiming to eliminate such diseases, and by your example and precept you have helped in bringing the public to understand and appreciate that the concerted action of yourselves and your colleagues in authority is always for the best interests of the many, even though at times it may seem to bear hard on the individual.

I anticipate no dissenting voice when I say that the most important ally of the public health authorities is the medical profession, nor do I fear contradiction when I maintain that allegiance is of the highest value only when willingly given for intelligent reasons.

NEED OF DISCRETIONARY POWER.

Such being the case, the importance of a clear mutual understanding of the objects and desires of the several arms of this organization becomes at once apparent.

The arbitrary enforcement of cut-and-dried regulations, many of which are obsolete and unsuited to modern demands, by individuals not trained for the service, unacquainted with the advances in preventive medicine, devoid of sympathetic interest in the evolution of medical ideals, and consequently lacking in public and professional confidence, has led too often to an estrangement between the body in authority and those from whom it should receive support, with a result, needless to say, that is fatal to everything in the way of progressive administration.

When we contemplate the rapid advances in knowledge on the manifold phases of disease we are at once impressed with the fact that, excepting such statutory regulations as are of the most general and basic nature, none that can be enacted are likely to prove of permanent service. Some must be revised to meet the modern demands and new ones formulated adaptable to unexpected contingencies. The framing of such rules and regulations as shall be based on common sense, harmonious with scientific requirements and in accord with established sanitary precepts, falls, as a rule, on those

* Delivered before the Philadelphia County Medical Society.

responsible for their administration, but they are rash men who will undertake this task without the support of those who see intimately and constantly many phases of the subject that they, by reason of circumstances, can view only from a distance.

A limited practical experience with public health matters has convinced me that, where a close and intelligent co-operation between the medical profession and the body in authority exists, the interests of the community are best served by giving to those in authority absolute power and by holding them rigidly accountable for the judicious exercise of such power. This may seem a startling proposition, but I can assure you that it is not made without due reflection, nor without discouraging experiences with specific, inelastic statutes unsuitable to newer conditions, but unchangeable without special legislative action.

The regulations formulated by the body in authority should have the force of laws, and it should be possible promptly to amend, modify or repeal them as conditions dictate.

Powers of that magnitude are of advantage in several ways, viz., the enormous responsibilities thus thrust on the authorities insure the utmost care in the framing of regulations; the abuse of such power reacts directly on those misusing it, and its possession by competent individuals permits of the framing of new and the revision or repeal of old regulations as the occasion warrants without the doubt and delay incidental to legislative deliberation.

This idea is not altogether new. In many particulars the original laws creating boards of health and quarantine boards gave to them general powers that are almost plenary, and I am not sure but that in a court of final appeal that power would be found to extend much further than would appear from the casual reading of those laws. However, as there may be some doubt as to the scope of the power conferred by the original laws, as subsequent laws only harmonized with the knowledge existing at the time of their enactment, and as the modern problem of public health, like all other medical problems of the day, assumes more or less of a new aspect with each advance in our acquaintance with disease, it seems wise to make provisions whereby laws may be promptly repealed, amended or otherwise modified to meet the needs of the ever changing subject comprehended by them.

CONDITIONS IN PHILADELPHIA.

When those at present responsible for the administration of public health matters in this city took office they were fully sensible of the responsibilities that were assumed, but were correspondingly ignorant of their powers to carry into effect certain propositions that were regarded both by themselves and their medical advisers as of fundamental importance to the successful and comprehensive performance of their duties.

An examination of the statute books revealed the existence of many excellent laws, some of them as good as could have been formulated at the time, but practically all of such a nature as to limit the authorities to certain specific lines of action. They contain no authorization for the exercise of personal judgment in the treatment of unusual individual cases and no revision or modification is possible without legislative approval.

A brief experience with such circumscribed authority soon demonstrated the impossibility of carrying into effect many modern views concerning the scope of the work, and many trials at modifying the existing laws

made evident the unlikelihood of satisfactory results. It was, therefore, decided to petition the state legislature to confer on the health authorities of cities of the first class in this commonwealth power to make regulations especially referable to the management of contagious diseases, regardless of existing laws, such regulations, when formulated and made public, to become laws susceptible of modification, amendment or repeal, as experience might dictate.

This request was granted, and as a result there are shortly to be put in operation a set of regulations that it is hoped may meet with your hearty support, since in framing them the utmost care has been exercised to safeguard fully the public health without working more than the minimum of hardship and inconvenience on the individual. While these regulations are issued as laws, it is true they are laws that may be modified or repealed as circumstances demand, and this, too, without the doubt and delay incidental to legislative consent. Therein lies the fundamental beauty of the act of 1905, under which we are at present operating. The new regulations differ in a number of particulars from those formerly in force, but this is made necessary by the demands of an ever-changing problem, of a progressive medicine and of an enlightened public.

PREVENTIVE MEDICINE IN THE PAST.

A comparatively short time ago the problem of preventive medicine, in so far as it concerned the health of the public, comprehended the suppression of only a small group of diseases having conspicuously epidemic tendencies. Little or nothing was known of their causation, scarcely more of the manner in which they were disseminated, and the means for their prevention, barring smallpox, were in the main empirical. The mildly contagious diseases, ever present in all populous centers, were not taken seriously; their existence was viewed as a matter of course, and as they were not conspicuously fatal they were accorded no official recognition. Tuberculosis, the most frequent cause of suffering and death, was considered an heirloom, dangerous only to the afflicted individual, and for him hopeless, unless amenable to cod liver oil and climatic treatment. The so-called miasmatic diseases, especially malarial and yellow fevers, were not supposed to bear any direct relation to other cases of the same diseases, and the channel through which such relation is established was scarcely more than suspected.

The important advance of recent years in our knowledge of the natural history of disease, especially as regards causation, modes of dissemination and methods of prevention, constitute one factor in forcing a different attitude toward transmissible diseases in general, while the demand of an enlightened public for a progressive and comprehensive consideration of the subject may be regarded as the other.

MODERN PUBLIC HEALTH ORGANIZATION.

As the successful solution of this problem depends fundamentally on a clear conception of its scope, not only by those officially responsible for its solution, but by those to whom they look for aid, it is appropriate at this time to indicate, possibly in some detail, the objects, aims and accessories of a modern public health organization.

In a word, the primary object of such organizations is to safeguard the public health by direct attention to preventable diseases. According to the tenets of modern medicine and the dictates of common sense, any disease that is transmissible from person to person should be, to

more or less extent, preventable, particularly if its exciting factor and the manner in which it is disseminated be known. If this dictum be admitted, it then becomes the duty of all interested in the prevention of disease to take into consideration not only the comparatively small group of conspicuously epidemic diseases, as formerly, but to enlarge the list to include all types of sickness that are known to be transferable from person to person.

Such is, in fact, the modern tendency. But in the practical application of means to the end the work may be fairly regarded as yet in the experimental stage. At the present time it is customary to consider diseases according to the degree of their transmissibility, those of a dangerous and highly contagious nature being surrounded by safeguards that are not thought necessary to the milder forms, while others are surrounded by no apparent safeguards at all, unless the educational methods practiced in connection with them be given their due value.

NOTIFICATION NECESSARY.

That such preventive measures as are appropriate to the exigencies of the particular type of disease encountered may be taken, it is necessary that all existing cases of transmissible disease be regularly and promptly recorded at a central bureau. Such notification falls to the practitioners of medicine of the community.

Here is encountered the first obstacle to correct administration, though I am glad to say that in this community it has never reached serious proportions. Nevertheless, questions often arise that it is of importance to our mutual understanding to discuss here. The commonest of these questions relates to the desirability of recording *all* types of transmissible disease. The principal reasons for recording all communicable diseases may be briefly summarized as follows: 1, that those in authority shall know definitely and at all times the exact disease situation in the community, otherwise the functions for which they are responsible can not be satisfactorily performed; 2, that local predisposing or exciting causes, possibly accountable for the origin and perpetuation of disease to a greater extent in one part of the community than in another, may be detected and, if possible, eliminated; 3, that immediate measures may be applied to those diseases admittedly demanding the utmost promptitude in official action; 4, that a correct and complete record of location and environment may be kept of those diseases less urgently requiring official supervision; 5, that appropriate educational measures may be employed in connection with the less dangerously communicable diseases; and, 6, that all channels through which disease may be carried from the infected premises may, if possible, be cut off.

The manifold uses made of such data as are here requested would be impracticable for a private practitioner, even were it his duty to utilize them in a comprehensive way. Successful practice of public preventive medicine is impossible without a prompt and correct registration of all types of transmissible disease, and there is no feature of the work more urgently demanding the conscientious co-operation of the private practitioner.

An occasional practitioner has regarded it as a hardship to be asked to report such cases, especially since he receives no compensation for it. Surely such complaint is made without reflection. For sake of argument let us assume that the general practitioner encounters on an average one case of reportable disease a week (a high estimate, I take it). Is it a very great hardship for him to fill out the spaces on a post card, supplied to him

without cost, and mail it at a convenient post box? The whole operation should take but a few minutes at most.

As to the matter of compensation, is he not already paid, in this city at least? Is it forgotten that antitoxin for the treatment of diphtheria among the poor is gladly supplied him without cost whenever he demands it?

Is it forgotten that all of his cases of suspicious sore throat may be examined bacteriologically free of expense?

Is it forgotten that vaccine virus for use among those unable to pay for it is distributed gratuitously, and that vaccinations are performed, free of expense, by experts in the work whenever the request is made?

Is it forgotten that he is aided, again without expense, in the scientific study of supposed cases of typhoid fever?

Is it forgotten that the services of trained diagnosticians are to be had on demand in connection with all cases of supposedly contagious nature, and this, too, at no cost to either physician or patient?

Is it forgotten that the disinfectors of the health department are at his bid and call for all work properly coming within their province?

In short, is it realized that the entire machinery of the Department of Health stands ready to do for the public welfare anything within the scope of their duties that may be requested by a practitioner?

As I see it, there is compensation, and compensation in abundance, for the limited service that is required.

The importance of prompt, concerted action in the matter of reporting disease has been brought to our attention in a very forcible manner within the past three weeks. The incident is of such instructive nature that I venture to detail it. On October 20 the Bureau of Health was informed that there were several cases of typhoid fever in one of the students' boarding houses in the city. Simultaneously with that report came others from physicians practicing in the vicinity of the boarding house. The total number of cases occurring within a few days of one another, and in most instances in the surrounding neighborhood, is thirty-nine, all of which, when the necessary data were obtained, were found to receive milk from the same source. Two brothers supplying the milk were taken, practically from the delivery wagon, to hospitals, both suffering from typhoid fever. Further inquiry developed the fact that both brothers, up to the time of admission to hospitals, had been filling their milk bottles from the original cans by sucking the milk, with the mouth, through a rubber tube, and thus syphoning it from the cans into the bottles in which it was delivered to the customers. It seems to me that this is information of some value to the public. But when I tell you that twenty-four physicians and three hospitals were concerned in those thirty-nine cases of disease, and that none of the physicians reported over two cases, you may readily perceive how unlikely it would have been for us to have discovered the cause of the trouble had there been no notification, or only notification by a small number of the practitioners seeing the cases. There would have been little or nothing to attract attention, for the existence of two or three cases of typhoid fever in the practice of a single physician, in a city in which typhoid fever is disgracefully prevalent, is not apt to be unusual. It is not reports from one or a few men that are wanted; it is reports from all, and the aggregate of reports constitutes the datum that is of real importance to the work.

Inspection.—Complaints frequently reach the health authorities to the effect that their representatives are

officials; that they call at the houses from which cases are reported and ask many questions. The authorities readily assume the responsibility for questions asked, and they take great pains to instruct their representatives to pay due regard to the rights of the family physician when asking the questions. All questions authoritatively asked by an inspector who is detailed to secure data on a reported case have been duly considered and formulated by the responsible heads of the department. They bear on what may be called the sanitary history of the case, and the answers to them are of vital importance to the discovery of sources of infection common to groups of cases. They are not left to the inspector, but are on a printed blank, and embrace so many phases of the subject that were the physician in attendance asked to formulate them or to reply to them he might with justice complain that a hardship was put on him.

The Placard.—In the course of the customary official management of contagious diseases a bone of contention that has ever stood conspicuously to the fore is the use of the placard. It is not my intention to open the debate on this subject, but rather to state a reason, perhaps the most important reason, why the use of the placard is continued in the new as in the old regulations. This is best done by the recital of a personal experience. Some two years ago a medical friend in whom I have the fullest professional confidence, and for whom I have a warm personal regard, called at the bureau in something of a state of mental perturbation. He told me that two of his children were down with scarlet fever; that from the onset of the disease they had been perfectly isolated in the top story of the house; that a trained nurse had been secured to attend them; that there was absolutely no communication between these cases and the remainder of his family, and that he would be personally responsible for the continued quarantine of the cases until they were well if the placarding of his house could only be omitted. As he enjoys a large and lucrative office practice, as I had no doubt of his sincerity, and as I was new at the business, I consented to omit the placard. Within two days I received messages from two of his patients that gave me, I can assure you, a most uncomfortable few minutes. The complainants stated that they would under no circumstances have visited his office had they known of the existence of contagious disease in the house, and that as citizens they demanded of those in authority due notice of where dangerous diseases exist. It is evident that if the placard does nothing else it at least satisfies this reasonable request.

Vaccination.—For the past few years the health authorities of the United States have been greatly exercised over the occurrence of smallpox. The disease has prevailed in varying degree in almost every state of the country. Could there be a less flattering commentary on our vigilance and intelligence? With a method at hand for the absolute prevention of that malady, the responsibility for its existence falls directly on our own shoulders.

You may perhaps be astonished to learn that since the advent of smallpox in Philadelphia, in about 1898, there have been vaccinated at the public expense approximately 600,000 persons. Many of these had never been vaccinated at all, while many of the balance had submitted to the operation at so remote a date as to make doubtful the protective value of the vaccination. This figure includes none of the persons vaccinated by physicians in their private practice.

In addition there has been maintained, also at the

city's expense, a hospital for the reception of a disease that should never exist and would not exist were we to perform unrelentingly our duties to the public. The two items of emergency vaccination and special hospital maintenance constitute a financial obligation that no enlightened community should be forced to assume. If vaccination and re-vaccination be rigidly enforced as a routine measure, I see no reason for the maintenance of expensive hospitals and the support of experts to care for smallpox patients. The few cases that might be imported from beyond our boundaries would cause no alarm, and they could easily be managed in simple temporary, but efficient, quarters.

While on this subject it is important to invite your attention again to an instructive experience gained in the course of official work. The routine medical examination of public school children now practiced by the medical officers of the bureau of health has revealed a practice that, to put it mildly, can scarcely be deemed commendable. Hundreds of children, having no sign whatever of vaccination, but still holding certificates of successful vaccination, have been discovered in the schools. The great majority of the certificates had been signed and issued by the physician at the time the operation was done and without subsequent verification. The exclusion of the child from school as a protective measure is, under the circumstances, imperative, with the result that it loses valuable time, while the physician at fault loses the confidence of its parents. The remedy for this is too obvious to require comment.

Diphtheria Antitoxin.—Scarcely less important than the value of vaccination in preventing smallpox is the prophylactic use of diphtheria antitoxin in combating the dissemination of diphtheria. The protection afforded, though temporary, is nevertheless absolute. In consequence this agent has become a permanent adjunct to the armamentarium of those concerned in public preventive medicine. The statistics of this community do not warrant the opinion that antitoxin is as widely used by physicians for the prevention or even the treatment of diphtheria as its value demands.

Hundreds of cases of typical diphtheria in the fourth, fifth and sixth days of the disease arrive at the Municipal Hospital annually without ever having had a single dose of antitoxin. Many of these cases had been seen by physicians, and yet the Department of Health is making every effort to encourage the more extended use of this agent. It is supplied without cost for use among the poor, and the medical officers of the bureau may be called on to administer the remedy free of charge whenever a physician so desires it. Did we take the pains to inform the public at every appropriate opportunity that the spread of diphtheria throughout a household or from one child to another can certainly be prevented by the injection of a small dose of antitoxin, its use would be more general; fatalities would be decreased in number, and the incidence of the disease enormously lessened.

Further Preventive Measures.—The opinion is growing among those who reflect on the subject that certain highly-contagious diseases may be and often are carried from one house to another by physicians, nurses, clergymen, undertakers and others who may have been in contact with them during the performance of their respective duties.

Such an accident is as little desired by the profession as it is by the laity and by those responsible officially for the public health, and as its prevention necessitates the taking of simple, common-sense precautions, it becomes the duty of those in authority to encourage in

every way all efforts to safeguard the public against such accidents by appropriate recommendations. The regulations authorized by the legislature of 1905 bear on this point—not in the way of rigid requirements, but as suggestions that it is believed will meet with the approval of all who are sincere in their efforts to co-operate in this work.

Hospitals.—Of all the auxiliaries essential to the safe conduct of this work, probably none is of greater importance than properly equipped hospitals. Such hospitals should contemplate not only the reception of cases that are unable to pay for medical care, but of pay cases as well, and in order to insure the use of the hospital by the latter there should be regulations permitting the medical care of such patients by their own private physician if it be so desired.

Such hospitals, for all diseases except smallpox, should be conveniently located, should be modern in equipment, should be attractive to the eye and in no sense suggestive of a pesthouse, and should be manned by men known to be experts in the management of the diseases that they are designed to receive. Every effort should be made to transfer patients suffering from contagious diseases to such hospitals.

Under the best of circumstances, even in hospitals, the complete isolation of certain diseases of this class is attended with difficulty; how much greater then does this become when they are at their homes often under the supervision, during the absence of the physician, of sympathetic though perfectly incompetent friends or relatives. Under ordinary conditions I believe it safe to assume that the progressive incidence of contagious diseases in a community is in direct proportion to the number of foci, i. e. of infected private premises, in that community. The lessening in the number of such foci by transference of cases to hospital is largely in the hands of the family physician. His advice will go far toward the accomplishment of the desired end, and in most cases such advice, I am sure, would be given had we appropriate accommodations for the patients.

In the majority of instances I believe a busy man in general practice would gladly be relieved of the responsibilities and annoyances of patients sick of dangerous communicable diseases were there suitable hospitals for their accommodation. The health authorities want your co-operation in efforts to secure for Philadelphia hospitals for the care of contagious diseases, not makeshifts or pesthouses, but modern institutions commensurate with the dignity of our city and of the utmost importance to the proper control of contagious diseases.

Disinfection.—In still another direction can the private practitioner be of substantial aid in the campaign against disease. There is no longer any doubt of the value of disinfection, cleanliness, sunlight and fresh air in destroying and eliminating contagion. Opinion on this subject is securely established on experimental evidence, statistical proof and wide experience. The routine disinfection and cleansing of premises occupied by the highly contagious diseases is approved and demanded by all, but the case is somewhat different with the less dangerous, though time-consuming, maladies of transmissible nature.

Much could be done toward lessening the incidence of the latter were similar measures taken in connection with them. Many of the laity do not comprehend the desirability of such action. A word from the medical advisor will serve to impress them with the need for it. In connection with the transmissible diseases that run a protracted course (I have tuberculosis in mind) fre-

quent disinfection and cleansing by simple but efficient and appropriate methods will go far to lessen dissemination. As a general safeguard I believe that every house or apartment that has been vacated by a family, regardless of the question of disease in that family, should be disinfected before being let to others. This the Bureau of Health stands ready to do without cost to owner or agent and looks to you for co-operation in this suggestion.

The Creation of Public Sentiment.—Finally, it may safely be said that unless the public comprehends clearly the importance of the end toward which we are all striving, and appreciates the relation of all measures to that end, but little progress can be made. The campaign for the health of the people is essentially a campaign of education. Enlighten the people on all phases of the subject and at every opportunity, and the work will progress smoothly. Keep them in ignorance, surround the subject with mysteries that cannot be comprehended by a plain man, and no laws that are enacted or powers that are conferred will suffice to accomplish the desired result.

NATIONAL QUARANTINE A REASONABLE FUNCTION OF THE GOVERNMENT.

L. SEXTON, M.D.
Tulane University.
NEW ORLEANS.

The preservation of the health of the people of the United States is a function, within the scope of the duty of the national government. It bears a close relationship to the efforts put forward by the national government toward preventing the spread of epidemic diseases and finds its counterpart in the methods adopted to prevent the destruction of forest trees in the New England states and the destruction of the fruit industry on the Pacific slope.

The care of the health of its citizens, the keeping out of bubonic plague, Asiatic cholera, and yellow fever are certainly as important as carrying out the measures above mentioned, in which the government has undertaken control.

The suggestions contained in this paper, which will be mostly in reference to yellow fever, will apply as well to bubonic plague in California, to Asiatic cholera in New York, or the isthmus of Panama.

Every other health consideration along our Mexican gulf coast line dwindles into insignificance in comparison with yellow fever and the quarantines incident to the introduction of yellow fever at some of our southern dependencies. Previous to 1900 we thought these yellow-fever outbreaks dependent on fomites (whatever that may mean), but in 1905, in Louisiana, Mississippi and Florida, we went into the fight not blindly, but knowing our enemy and knowing that the sole propagator of the disease was the *Stegomyia fasciata* mosquito. It is needless here to go into details regarding what the world already knows; that we destroyed this insect in New Orleans at an expense to its citizens of one-quarter of a million dollars, made up by private subscriptions, to say nothing of the hundreds of millions lost in trade and commerce by the one hundred different varieties of quarantine, which we were called on to meet. Surely it is not reasonable or fair to suppose that this burden of

keeping out pestilential diseases from the entire United States rests on the citizens of one municipality or state, who are already taxed to the limit in maintaining levees to keep from being drowned by the floods of the great watershed of the West.

Uniformity of detention from infected parts would be one of the results we might expect from national control. Herefore, each state has been a law unto itself, some adopting five and others six days' detention from points of departure, as seemed most feasible to the various boards of health. With a national law all this could be regulated so that no city, in its greed for trade, could let down the bars so as to let in infection. Because of the close railroad connection between the gulf cities, passengers can land at one port, and within five hours be in the next gulf city, thus nullifying the action of the board which required six days' detention.

Persons leaving Havana on fast steamer can go to New York and return to New Orleans within less than the six days' detention necessary at the New Orleans quarantine station; hence, New York and all other northern ports should really adopt this six-day detention or infection from yellow fever would become liable through the laxness of their quarantine.

If the national government were responsible for the inspectors in all the foreign ports, and if these were properly selected from the Army, Navy, Marine-Hospital Service or any national quarantine service and ordered to report the first outbreak of fever in Mexican and South American countries on pain of dismissal if their reports were not correct, it would keep the health guardians in constant touch with all ports from which infection comes.

A part of the duty of these inspectors might be to educate these countries in the destruction of the infected *stegomyia* mosquito, as on its complete destruction depends the annihilation of the yellow-fever plague, as a case of yellow fever would be incapable of developing the infection in others, without the mosquito to serve as the intermediary host.

It is not beyond the range of possibilities to exterminate the disease by the destruction of all the *stegomyia* and their breeding places; or by the screening for the first three days of all yellow-fever patients in all countries in which the disease is endemic. This would require the concerted action of all governments in South American countries, including Mexico and Brazil.

Compacts between state boards have not been kept as agreed to. To acknowledge the existence of yellow fever in a community is practically to shut oneself out from the outside world, and this is a hard thing to expect of the average community. Quarantine has been so destructive to trade that commercialism and politics have dominated some boards and forced them to take chances with the suppression of the first cases of yellow fever in the vain hope that it would not spread on account of the lateness of the season or the special efforts made to destroy the first infected mosquitoes.

Any city that has experienced the rigors of shotgun quarantine will resist the announcement of yellow fever until there is indisputable evidence of its existence. The first few days of an attack of yellow fever and one of malaria run such parallel courses that all the acumen of the best yellow-fever experts is at times put to the test in differential diagnosis of the severe forms of congestive or *civo-autumnal* malaria and yellow fever. Hence, boards of health, in trying to deal honestly with the outside world, are often excusable for delay in coming to a conclusion.

GOVERNMENT INSPECTORS AND PHYSICIANS SHOULD BE REINFORCED BY LOCAL MEN.

It would be nearly impossible to get the best co-operation of the medical men of any community (without which no law would be a success) unless some of the men should be selected from the various communities and accustomed to the diagnosis and treatment of the diseases with which they had to deal. The position of inspector or diagnostician of any health organization is not a happy one.

To declare that there exists in a community a contagious disease, which means loss in trade and all the inconvenience of quarantine, and to stand firm by the diagnosis, to keep track of recurring cases, and to keep a municipality locked up when all its inclinations are to be free, requires the strongest kind of physical and moral courage.

During the epidemic of bubonic plague in San Francisco the lot of the Marine-Hospital Service men was not a happy one. Between locating cases and dodging bricks they led rather strenuous lives.

The uniform of the government, under such circumstances, is required to enable the health guardian to command the proper respect and protection. Men in this service should be entirely divorced from practice; they should be sanitarians and not practitioners.

How few of the ordinary political physicians who get appointments are really trained sanitarians? In many cases these men are selected more from the number of votes they can poll at the next election, rather than from any sanitary acquirements they may possess. Sanitary experts should always be divorced from national and local political and commercial influences.

There is no doubt that the United States uniform commands attention and respect, which is not given to the state official.

People stand in awe when the United States Government is behind a movement. In the recent outbreak in New Orleans, citizens permitted representative inspectors of the government to visit each bedroom in their premises in search of fever, whereas, no such freedom of investigation would have been tolerated for a moment from the state officials without the government uniform. While under ordinary circumstances we do not advocate the invasion of a man's premises, this becomes absolutely necessary in getting correct data in a cosmopolitan population, where to deny the existence of disease is no uncommon rule.

While this is an apparent encroachment on personal liberty and the accepted theory that "one's house is his castle," such stringent investigation is absolutely necessary, in order to be thorough in the suppression of epidemic diseases in cosmopolitan cities. As stated before, the greatest obligation a government owes to its subject is the preservation of the health of its people.

Our ports fronting on the Gulf of Mexico and on the Atlantic and Pacific Oceans should not be expected to bear the entire burden of the protection of the interior states from Asiatic cholera, bubonic plague and yellow fever. New Orleans should not be called on to contribute one quarter million from private citizens, as was the case in 1905, but all the interior states should help to keep out pestilential disease just as if the entire country were invaded by a foreign foe.

This is really the only way to make the burden of quarantine regulation bear equally on all. If all the states keep up separate quarantine stations, medical offi-

cers and paraphernalia, which costs an average of from \$75 to \$100 per vessel quarantine charges for every ship that enters our port at New Orleans, it makes the expense a hundred times greater than if the government or one central head should have charge of the entire regulation of quarantine matters.

To illustrate, Port Limon has had a medical inspector from the Marine-Hospital Service, one from Mobile and one from New Orleans, all watching for suspicious cases of yellow fever. If all this effort had been concentrated under a national quarantine service, removed from all political affiliations, there would have been a great saving in salaries and men.

The destruction of all the stegomyia and anopheles mosquitoes in the United States would mean the abolition of yellow fever and malaria. This contract is certainly large enough to be a government job and should be under its health department, and while we may never live to see this accomplished, a great deal can be done toward this end by draining the marshes and lowlands, thus rendering them suitable for cultivation. At present they are only the breeding places of these disease-carrying insects.

The building of the Panama Canal does not outweigh in importance the destruction of these two varieties of mosquitoes, for, while periodical outbreaks of yellow fever invade the country only in our southern states the anopheles mosquito is getting in his malarial work over nearly the entire area of the United States, and nearly all the time, and malarial fever kills its thousands where yellow fever kills one.

The destruction of anopheles or malarial mosquito is certainly, therefore, a national subject. The *Stegomyia fasciata* variety could be exterminated by oiling and screening cisterns and receptacles holding water and by putting open gutters in cities underground. The swamp mosquito (or anopheles) could be eradicated by draining or filling in our marshes.

It takes a malarial or yellow fever patient and a stegomyia or anopheles mosquito to propagate or to spread either of these diseases.

NON-POLITICAL CONTROL.

In nearly all the states' governments throughout the Union, regardless of which party is in control, there has grown up an office-holding syndicate which at each approaching election farms out or promises political jobs to medical health officers who control the greatest number of votes, regardless of any qualification or experience these men may have in dealing with health and quarantine matters; hence, changes recur with each election period, and health officers are deposed just about the time they are becoming efficient. I do not pretend to claim that a great many worthy and honorable medical men have not been chosen in the past to manage our health affairs; yet the reasonableness of the argument of divorcing all such appointments from a political spoil system is too apparent to need argument at my hands. Health officers should be protected by civil service rules so long as they are efficient and competent to do the work in hand.

As to whether the national quarantine should be under the supervision of the Marine-Hospital Service or under the control of the Navy or Army medical service or under a cabinet health officer, we leave others to argue, but that maritime quarantine should be in the hands of the national government we are thoroughly convinced.

ULCEROMEMBRANOUS ANGINA (VINCENT'S ANGINA) AND STOMATITIS.*

RUTH TUNNICLIFF, M.D.

AND

RUTH TUNNICLIFF, M.D.

CHICAGO.

The disease to which attention is here directed has been described under several names, "ulcerative angina and stomatitis," "ulceromembranous angina and stomatitis," "pharyngitis ulcerosa," "angina diphtheroides," "angina exsudativa ulcerosa," "Vincent's angina," "angina chancreiforme," "pseudomembranous angina," "spirochätenbacillen angina," etc. The name selected for the title of this paper is preferred as designating the principal characteristics of the process, i. e., ulceration and formation of a pseudomembrane. This is not a wholly satisfactory name, as frequently there is no ulceration, a pseudomembrane only being formed, as was observed by us in several cases. Vincent's name is not properly used to designate the angina, since it had been described¹ previous to his studies by French and Russian clinicians (Barthez and Sanné, Simanovsky, Nevejin, Moure and Mendel). All of the cases described are separated sharply by certain clinical and bacteriologic characteristics. On the affected mucous membrane there appear pseudomembranous formations and, as a rule, ulcerations. In the exudate are found fusiform bacilli usually in association with long spirilla.

ETIOLOGY.

Age.—The majority of cases reported have been in young adults between 18 and 25 years of age. Athanasius's cases were in children between the ages of 26 months and 13 years. The patients we observed were children.

Sex.—Males are said to be more often affected than females, according to most observers. This is probably due to the fact that many of the patients have been soldiers and medical students. The majority of our cases were in girls.

Predisposing Causes.—The use of tobacco; trauma of the mucous membrane, as after tonsillotomy; eruption of a wisdom tooth; defective teeth or those covered with tartar; alveolar abscesses; gums of scorbutics; syphilis and mercurial stomatitis are said to predispose to this disease. It is said to follow the acute infectious diseases. Two of the cases studied by us followed scarlet fever, one followed measles and one whooping cough. Twice the condition was present at the onset of scarlet fever. The teeth were covered with tartar in the majority of our cases. Chronic enlargement of the tonsils and adenoids were present once. A previous history of alveolar abscess was obtained in one patient.

Bacteriology.—According to Tarassiewicz, as quoted by Mayer, the first observer to note the association of the fusiform bacilli and spirilla with a disease process was Raubhus. In 1893 he presented cases of ulceromembranous angina in which he demonstrated pointed bacilli and spirilla and his photographs appear to show them to have been identical with those described by subsequent writers. Plaut, in 1894, described the organisms

1. From the Memorial Institute for Infectious Diseases, Chicago.
1. References to authors have been omitted, since a complete list of the publications can be found in the following recent articles: H. Böttke, *Contrib. f. Bakt., Erste Abt., Referate*, 1904, vol. xxxv, p. 1; Weaver and Tunniff, *Journal of Infectious Diseases*, 1905, vol. II, p. 446; Berkeley, *Medical News*, 1905, vol. lxxxvi, p. 576.

in five cases of ulcerous angina. Vincent, in 1896, described the fusiform bacilli and large spirilla in cases of hospital gangrene, and stated that the same organisms were found in certain anginas of an ulcerative type. Bernheim, in 1897, reported 30 cases of stomatitis and angina, in all of which he had found fusiform bacilli and spirilla. He appears to have been the first to point out the identity of certain cases of stomatitis and angina from the common etiology. Vincent, in 1898, reported a further series of 14 cases of ulceromembranous angina in which the organisms were present. These early reports have been followed by a large number of corroborating observations which testify to the occurrence in preponderating numbers of fusiform bacilli and spirilla in certain cases of stomatitis and angina. A large number of these observations have been recorded in French literature, many in German and American, and a few in English. They indicate the wide distribution of the organisms in question. The infrequency with which the disease has been recognized has probably been due to failure to make direct examinations of the exudate from pseudomembranous lesions of the mouth and throat. Because diphtheria bacilli are not detected with any certainty by such examinations, the custom of depending on cultures quite exclusively has become almost universal, and as the fusiform bacilli and spirilla do not grow to any extent on the medium usually employed for the detection of diphtheria bacilli they have been largely overlooked.

In ulceromembranous anginas, the two bacteria under consideration have been observed in association with diphtheria bacilli by Abel, Baron, Bernheim, Vincent, Niclot and Marotte, Auché, Simonin, de Stoecklin, Gallois and Courcoux and Oberwinter. Abundant fusiform bacilli but no spirilla were found together with diphtheria bacilli in one case by Beitzke and in 6 cases by Oberwinter. The latter author has observed 3 cases of diphtheria in which smears showed almost only fusiform bacilli and spirilla. That the organisms occur in syphilitic lesions of the mouth and tonsil is evidenced by the observations of Baron, Vincent, Freyche, Graupner, Hallopean and Apert, Salomon and Wolff.

Abel was successful in demonstrating both fusiform bacilli and spirilla in healthy mouths, especially between the gums and teeth. Gross found bacilli and spirilla in small numbers on the normal tonsils in 11 out of 13 persons. It is generally stated that the spirilla described in these cases are the *Spirochata denticola* of Miller.

In most of the reported cases, the bacilli and spirilla have been recognized in smear-preparations made direct from the seat of the disease, and in stained microscopic sections of tissues. Usually efforts to cultivate the organisms have resulted in failure. A number of investigators have grown the bacilli in mixed culture. Some also obtained a simultaneous growth of the spirilla.

The present description is based on the study of the organisms from the following sources: Two cases of ulceromembranous stomatitis, 4 cases of ulceromembranous angina, 1 case of pseudomembranous angina, 2 cases of combined angina and stomatitis, 1 case of noma of the cheek, 1 case of diphtheria, saliva and tartar from 18 healthy mouths.

Three of these cases, one of angina and one of stomatitis, and the one of diphtheria occurred in the wards for contagious diseases of the Cook County Hospital in the service of Dr. William L. Baum. Seven of the cases were observed in the Hospital of the Memorial Institute for

Infectious Diseases in the service of Dr. Frank Billings and Dr. Alexander F. Stevenson. To these gentlemen we wish to express our thanks for the opportunity of studying and reporting the cases. Two cases were observed in private practice.

In smear preparations made from the seat of disease, bacilli and spirilla were found which corresponded to those described by previous authors.

The bacilli are long, slender rods with pointed ends, somewhat larger in the middle. Sometimes the ends are rounded and the rod may be rather thick. They are sometimes slightly bent, and occasionally take the form of the letter S. The length is usually from 6 to 12 microns, but sometimes filiform elements of considerable length are encountered. The bacilli are usually scattered uniformly throughout the preparations and often occur as pairs end-to-end, sometimes forming more or less obtuse angles. At times they are seen in irregular clumps, or arranged radially about a common central point, or in rows somewhat similar to diphtheria bacilli. They stain fairly well with Loeffler's solution of methylene blue and anilin-water solution of gentian violet, but best with carbol-fuchsin. With the less intense stains, especially in the larger forms, there are often portions of variable size and shape which stain faintly. No motility could be detected.

Graupner has illustrated the bacilli with stained peritrichous flagella. He found that motility was rapidly lost, even under favorable conditions in 20 minutes. Beitzke explains the varying expressions regarding motility by this fact, but it is better accounted for by Ellermann, who cultivated the shorter, curved forms in pure culture and found them to be motile spirilla.

The bacilli do not stain by Gram's method. The number of bacilli is variable. In the earlier stages of ulceromembranous angina and stomatitis they are most abundant, and they decrease as the process of recovery advances. When the bacilli and spirilla are most abundant, other forms of bacteria are present in small numbers. As the two organisms decrease, the associated bacteria usually increase. In normal mouths the fusiform bacilli were present in small numbers in smears from saliva, tongue and gums. In the case of diphtheria examined, they were so few as to be found only after considerable search.

The spirilla, also spoken of as spirochete, which are associated with the fusiform bacilli in a large proportion of instances are long and delicate, and present three or four turns. They stain uniformly and much less intensely than the bacilli, and in faintly-stained preparations might be overlooked. They do not stain by Gram's method, being much more quickly decolorized than the bacilli. They are usually quite actively motile, but sometimes not. The association of spirilla with the bacilli was observed in all the cases studied. In general they were in numbers corresponding to the number of bacilli. In the mouths of many healthy persons what appeared as the same spirilla were found, especially about the gums, often in enormous numbers.

Most authors believe that the fusiform bacilli and spirilla are entirely distinct varieties of bacteria, and consider that they act in symbiosis, the spirilla serving to enhance the virulence of the bacilli. Vincent, Niclot and Marotte, Baron, Hess, Oberwinter, etc., have observed that those cases of ulceromembranous angina in which only the bacilli are found are milder than those in which the two organisms are associated. In cases in which deeper destructions of tissues occur, the spirilla

are said to be constantly present. In the case of noma from which material for study was obtained, fusiform bacilli and spirilla were present in the nasal discharge from the beginning, and later in the ulcerative lesions of the gums and cheek.

Some observers have maintained that the bacilli and spirilla are different forms of the same organism (Seiffert, Perthes, Sobel and Herrman, Krahn). Most authors do not agree with this, but consider them two distinct organisms. After careful examination of many preparations, both direct from man and from pure and mixed cultures, we have been unable to find any appearances which would support these assertions.

From many of the cases the fusiform bacilli were grown in mixed cultures and from a few in pure cultures. They are obligate anaerobes. Details regarding these cultures are to be found in a former publication.¹ The spirilla have never been cultivated except in mixed culture.

Although the organisms described are found in association with characteristic lesions, the proof that they are the essential etiologic factors is not entirely complete. Further study of pure cultures may be expected to shed more light on the subject.

PATHOLOGY.

Athanasiu and others divide the affection into three periods: the onset, characterized by congestion and edema, the formation of the false membrane and finally the period of ulceration. In the majority of cases these three periods can not be distinguished.

The primary location of the disease is usually on the tonsil and edge of the gums. It may extend from these locations to the tongue, lips, even the soft palate, pharyngeal wall and cheek. The stomatitis and angina may occur simultaneously, but each is also observed alone. Extension beyond the common primary locations is not the rule. The deposits on the tonsils are usually irregularly oval or circular. It may be bilateral, but is usually unilateral. The pseudomembrane may be grayish, whitish, yellow, yellowish-brown or greenish in color. It is sometimes described as resembling the pseudomembrane of diphtheria, but usually it is thick, cheesy and friable in character. It may be marked by small hemorrhages (Hecht). The false membrane is usually readily removed, leaving a superficially abraded surface which bleeds easily and becomes again covered by an exudate in a few hours. With the progress of the disease, the ulcer may become much deeper, but shows little tendency to extend laterally. Sometimes the destructive process extends more deeply, leading to the destruction of the tonsils, uvula and parts of the pharyngeal wall (Baron, Bruce and others) As a rule, only one ulcer is present, but sometimes several are observed. The ulcers may become confluent, as was seen in one of our cases. They may be round or oval. The borders are pointed and irregular. The floor of the ulcer is uneven and later shows granulating points. They vary considerably in size. Sometimes the ulceration is very superficial or absent. There was none in three of our cases. The anginas have been classified by Vincent and others as croupous or membranous and as ulcerative, according to whether the ulcerative process is slight or prominent. The surrounding mucous membrane is red and slightly or considerably swollen. If the lesion is not observed at the outset, there appears to be no inflammation.

The submaxillary and retromaxillary glands are usually swollen, corresponding to the location of the disease in the mouth or throat. The swollen glands are firm, a

number of small ones usually forming the mass. There is, as a rule, no periadenitis. They rarely suppurate. Raoult and Thiry claim that the glands are rarely swollen except in badly cared for cases, and use this fact as an aid in diagnosis.

Healing takes place slowly after 3 to 45 days. The swollen glands often remain enlarged for some time.

SYMPTOMS.

The symptoms vary much with the severity of the disease. Often there are no symptoms or only slight ones, and the lesion is found accidentally. The following symptoms may occur at the onset: Feeling of dryness or discomfort in the throat, dysphagia, lassitude, restlessness at night, loss of appetite, headache, coated tongue, constipation, sometimes diarrhea, vomiting, pains in abdomen, epistaxis, chills and fever. As a rule, there is little or no fever. One of our cases had a temperature of 103.2 F. In some of the other cases the tempera were high, but there were other pathologic conditions to explain it.

One to five days after the onset the local condition is observed. With it the chief symptoms are pain in swallowing, salivation and fetid breath. These do not always occur. Sometimes the dysphagia is slight. The breath may not be fetid if the case is mild or if antiseptic solutions have been used.

If the gums are affected the teeth may become loose. There may be bleeding from the gums, even if they are free from membrane.

Athanasiu speaks of earache and nasal discharge as occurring at this period. Oberwinter also often noticed a nasal discharge and urges the importance of this symptom in young children as directing attention to the throat. We observed a nasal discharge only once. In this case the organisms were found in the nose before they appeared in the mouth.

COMPLICATIONS.

Many observers have found no complications. Albuminuria, according to Simanowsky, is frequent, and Bruce and Simonin and others report cases in which it appeared. We observed it twice, but as the patients had scarlet fever it could be attributed to this disease. Herpes at the beginning was noticed by Baron. Conjunctivitis, which Athanasiu gives as a frequent complication, we observed three times. He also mentions anemia as a complication.

The other complications seen by us were gastroenteritis twice and noma of the cheek once.

The following complications have been reported according to Niclot and Marotte: Appendicitis, pseudoreumatism, arthritis, endocarditis, pneumonia, pleurisy, infectious purpura, polymorphous eruptions, edematous patch in temporal region, with discoloration and tenderness (Nicolle).

PREVALENCE.

The disease seems to be very prevalent, many cases being undetected because of the mild course. Rodella found the characteristic bacilli in about one-third of 2,000 cases of pseudomembranous anginas from which he examined microscopic preparations. Abel found the organisms in 6 or 8 cases out of several hundred suspected of being diphtheria, and Beitzke in 5 out of 58 such cases. Libblowitz found the fusiform bacilli in 6 out of 38 cases of ulcerative affections of the mouth.

CONTAGION.

Contagion in connection with this disease has been observed by Vincent, Dopter, Bernard and Anger and others, but for its occurrence close contact is apparently

required. Costa says that it may be communicated by means of pipes, pencils, etc. Small epidemics have been observed, especially in families. Seven cases occurred in the Memorial Institute within four months. There was no proof that it was transmitted from one patient to another.

DIAGNOSIS.

The diagnosis is made by the finding of the characteristic fusiform bacilli in the smears prepared from the exudate, usually in association with the long, more faintly staining spirilla. The organisms are not stained by Grams method. It is always necessary to exclude diphtheria by means of proper cultures, as the diphtheria bacilli may be associated with the fusiform bacilli. Syphilitic lesions must also be excluded by the history and associated signs of the disease.

PROGNOSIS.

The prognosis is usually good, but it must not be forgotten that considerable destruction of tissue may occur in rare cases, and that gangrenous processes and noma of the face may develop from these ulceromembranous lesions, as occurred in one of our cases. According to Vincent and Richardier, the prognosis is bad in children. Baron, Bruce and others have noticed a tendency for this disease to recur after partial or apparently complete recovery. We observed this once.

TREATMENT.

Filatov and Nevegin consider chlorate of potassium administered internally a specific for the disease. Crandall also found that chlorate of potassium did most good. Baron believes therapeutic applications of little use. Various antiseptic solutions have been used locally and tincture of iodine is spoken of with favor. Because of the anaërobic character of the bacilli, peroxid of hydrogen is most useful and should be applied directly to the seat of disease. Sobel and Herrman made use of a 3 to 5 per cent. solution of silver nitrate, applying it daily to the diseased areas. At the Memorial Institute success attended the use of peroxid of hydrogen, followed by the following solution:

PREPARATION OF A SERUM FOR THE TREATMENT OF EXOPHTHALMIC GOITER.*

[Contribution from the Huntington Fund for Cancer Research, Department of Experimental Pathology, Cornell University Medical College.]

S. P. BEEBE, B.S., Ph.D.
NEW YORK.

The serum treatment of exophthalmic goiter, or Graves' disease, is not new. In addition to the ordinary medicinal measures which have been employed, many attempts have been made to obtain some specific of animal origin which would work as beneficially in exophthalmic goiter as thyroid extract does in myxedema. A few of these attempts have been partially successful, and since I wish to compare the serum which we have used with that tried in previous experiments, I will outline briefly the present condition of the problem.

The fundamental ideas for serum therapy in this disease are, first, that the symptoms are caused by an hyperactivity of the thyroid gland, and, second, that the physiologic action of the thyroid secretion is to neutralize some toxin arising in the course of metabolism. With

our present knowledge the thyroid origin of the symptoms of the disease seems the most rational of any thus far proposed, and, while not committing myself to it absolutely, I shall accept it without further comment for the purposes of the present discussion.

The success attained in the thyroid extract treatment of myxedema suggested that a similar means be employed with exophthalmic goiter. Thyroid extract, it was soon found, aggravated the symptoms in nearly every case, and since the typical picture is that of an intoxication of thyroid origin, attempts have been made to neutralize the products of the excessive activity of the gland by providing an oversupply of the toxin with which it is supposed the thyroid secretion normally combines. Theoretically, this combination detoxicates both components. Among the earliest experiments to make therapeutic use of this idea was that of Burghardt and Blumenthal,¹ who injected into a patient suffering from exophthalmic goiter blood obtained from a case of myxedema. Two hundred and forty cubic centimeters of a mixture of equal parts of blood and salt solution were administered during a period of eight weeks, and during the treatment the patient showed very marked improvement. Theoretically, the blood of animals which have been deprived of the thyroid gland should contain an excess of the metabolic toxin, ready for combination with the thyroid secretion. Ballet and Enriquez,² and later Burghardt and Blumenthal,¹ used the serum of thyroidectomized dogs, both orally and by hypodermic injection, with beneficial results.

More recently, under the leadership of Moebius,³ such a serum obtained from thyroidectomized sheep has come into wide use. This serum is now a commercial product, sold under various names, such as thyroideetin, anti-thyroidin, etc. Some favorable results have been reported from its use, but in the hands of most observers the treatment has not been of marked benefit. The difficulties of practical application of such a serum as this are great. Animals react quite differently to thyroidectomy, and the impossibility of standardizing the serum, together with the great variation in the dosage and means of administration, may account for some of the discrepancies in the results. It must be said, however, that the nature of this toxin and its presence in the serum of thyroidectomized animals has not been satisfactorily investigated.

The other method, which depends for its efficacy on an inhibition of the thyroid by means of a cytolytic serum, has had thus far only a very limited trial and the results have not been encouraging. I believe there are good reasons why the experiments have failed, and these will appear evident during the discussion. Numerous investigators have endeavored to develop a serum having cytolytic action for the thyroid gland. The method of preparing the serum has been uniform in nearly all of the experiments, but the results reported are quite variable.

In this country the first attempts were made by MacCallum,⁴ who injected emulsions of dogs' thyroids into geese at weekly intervals until they were supposed to be immune. He obtained some characteristic effect on injecting the serum thus prepared into dogs, but in most cases the animals became very much emaciated and cachectic without showing symptoms due to hypothy-

* Read at the New York Academy of Medicine.

roidism, although many of the injections gave a fatal result. In only one case did he find any lesions in the thyroid gland. His work has been confirmed by Yates,⁵ who made an antiserum by injecting dogs' thyroids into roosters or geese. He could demonstrate no cytolytic effect *in vivo*, although he had good test-tube reactions.

Portis⁶ has worked along much the same lines. In his experiments goats were immunized to dogs' thyroids in three different ways: First, by using the crushed glands; second, by injecting the crushed gland, which had first been washed out with salt solution to free it from blood; third, by injecting the colloid matter prepared by Hutchinson's method.⁷

The serum was administered to three groups of dogs in doses of four cubic centimeters per kilo., with the following results: The first serum caused a tremendous reaction, with profound hemoglobinuria. The second caused a good reaction, but only a slight hemoglobinuria. The third group, receiving serum developed by injections of colloid, showed a milder reaction, but no demonstrable hemoglobinuria was noticed. A point of great interest attaches to the fact that the thyroids of all the animals receiving serum were found to be free from colloid matter. No other lesions were found.

Some interesting and important observations have come from the foreign laboratories. Slatineano,⁸ working with a serum made according to the usual method, has been able to produce some changes in the thyroid epithelium, but never the lesions of chronic sclerosis. Following the feeble doses, he observed an enormous overproduction of colloid, which distended the vesicles and at the same time there was a diminution in the volume of the epithelial cells. With large doses subcutaneously, he obtained some necrosis of the glandular epithelium. When the serum was introduced directly into the carotid artery he observed a necrosis of the thyroid epithelium on the side corresponding to the artery injected; the vesicles were found opening into one another, while the colloid had completely disappeared. In the opposite thyroid, which had been in contact with less serum, he observed a complete disappearance of the colloid. These observations confirm a similar one made previously by Portis.

Two Belgian investigators, Demoor and Van Lint,⁹ have reported results so diametrically opposite to those of other students of the subject that it is difficult to believe in their accuracy. Their serum was made by injecting guinea-pigs or rabbits with an emulsion of dogs' thyroids. Their method was somewhat peculiar, in that they made their injections on every second or third day and bled the animals three days after the last injection, whereas the usual method is to make the injections at intervals of five to eight days and bleed six to eight days after the last injection. Demoor and Van Lint state that their method is essential to obtaining an active serum and that if the usual method was followed they failed to get results. Their experience in this respect is quite unique. It may be true, but it is contrary to the experience of other investigators, and it does not harmonize at all with my results with hepatotoxin and nephrotoxin, nor does it accord with the established principles of immunity. They also found that it is necessary to inject an emulsion of the whole gland in order to produce an active serum. Injection of iodothyroid, thyreo-

globulin or nuclealbumin did not yield an active serum. It is their belief that there is present in the whole gland some substance as yet unknown on which the development of an active serum depends. They state that when a serum made by their methods is given intravenously to dogs it causes all the symptoms of a strong and quickly fatal hypothyroidism. From a study of their methods and results I am inclined to believe that they were dealing with a hemolytic serum, which had little, if any, specific action on the thyroid gland.

The preceding summary of the more important experimental studies of thyroid cytolsins gives an uncertain basis for clinical application. Attempts have been made, however, to produce cytolytic serum having therapeutic value in the treatment of exophthalmic goiter. Murray¹⁰ has recently published his experiments in this direction, and, although they are faulty in many particulars, I have great respect for the honesty and accuracy of his conclusions. In his first experiment rabbits were fed on sheep thyroid extract for a month and the serum from the animals was then used in the treatment of two cases of exophthalmic goiter. The dose of serum was at first 5 minims once a day and later 7 minims three times a day, given by mouth. Both cases improved under treatment, but not more than might be expected from rest with the common medicinal measures. (It is open to serious doubt whether Murray could develop an antiserum by the method which he employed, viz., feeding thyroid extract to the rabbit.) In his later experiment Murray began by giving subcutaneous injections of sheep thyroid extract to a goat, but since so many abscesses resulted from this procedure he changed the method of administration and gave the extract by mouth for a period of two months. The serum from this goat was used in treating two cases. The serum was given by mouth, beginning with 5-minim doses three times a day and gradually increasing to 20 minims. In one case there was a gain of eight pounds in weight, but Murray concludes that the improvement noted in both cases was no more than usually takes place on ordinary treatment, and that no special effect could be attributed to the serum. It may be objected that the method of producing the serum in these experiments was faulty. The goat is not sufficiently far removed from the sheep as an animal species to serve well for such a purpose, and administration of thyroid extract by mouth has never been shown to develop immunity. Even though some degree of immunity had been obtained, there is no reason for supposing that it would be in any degree efficient for antagonizing the pernicious activity of the human thyroid gland, since its antitoxic properties would have been developed by a biologically different protein than the one it was expected to oppose *in vivo*. It would be quite as logical to use diphtheria antitoxin in the treatment of tetanus.

The serum which I have prepared has a somewhat different experimental and theoretical basis. During the last year I have been interested in studying the preparation and action of cytolytic serum having a higher degree of specificity than that which has been reported previously. A paper¹¹ has been published recently giving some of the results of this work, so I shall give here only a brief summary of it.

The cytolytic serum studied by other investigators has been made in nearly all cases by repeatedly injecting an organ pulp into the peritoneal cavity of some animal of an alien species. The serum thus developed may show

some antiaction toward the particular organ used for injection, but in most cases such action has been obscured by the very marked hemolytic and hemagglutinative properties. Indeed, Pierce¹² believes that much of the effect of the hepatotoxin and nephrotoxin developed by injection of the full cells is due to the agglutinated corpuscles forming small thrombi with resultant focal necroses. Practically all observers have noted a severe hemoglobinuria following the administration of such a serum. The results obtained have, therefore, justified the conclusion that it is impossible with such serum to cause definite lesions in one organ without at the same time injuring other organs. The serum has no morphologic specificity.

The cytolytic serum with which my experiments were made by was developed by injecting the nucleoproteids of some organ, such as the liver or kidney, instead of the whole organ ground to a pulp. The reasons for selecting nucleoproteids for this purpose are obvious. We know that the nucleus is the most important morphologic and physiologic part of the cell. If specificity is a function of any of the cell constituents, the nucleus must be most intimately concerned therein. They are the chemical basis for the most fundamental of the cell processes, and it seems to me that it is not unreasonable to suppose that by using only the nucleoproteids for the development of the serum a considerable amount of what we may call extraneous material has been excluded, and only those compounds have been included which have to do with the particular work of some selected group of cells.

Because of the biologic differences in proteids it is necessary to develop the serum from the proteids of the same species of animal as we use later for testing its activity; that is, nucleoproteids from dog organs were injected into rabbits at seven-day intervals until five injections had been made, and the serum from these rabbits was then tested on dogs. We could not expect such a serum to have much effect on the organs of cats or guinea-pigs. Test-tube reactions show that a serum made by injection of nucleoproteids is much more specific than the sera made from the full cells. The results obtained by the biologic test, however, are by far the most interesting outcome of the work, and in confirmation of the test-tube reactions show that such a serum is highly specific in its action. If the serum has been developed by injecting nucleoproteids from the dog liver, we find that its administration makes the animal very sick, and if the dose has been as much as 2 c.c. per kilo, the result is fatal. This dose is very much smaller than has been used by most previous investigators, but is still about 100 times larger than the dose of thyrotoxin, which we used later as a therapeutic dose in treating the exophthalmic goiter patients. Postmortem we find that the liver has been badly damaged, while the other viscera have not been injured. Other observers have found that a serum made from liver pulp invariably causes lesions in the kidney with albuminuria. The serum made from the liver nucleoprotein, on the other hand, has not produced renal lesions, and at no time has there been albuminuria following its use. However, if the serum has been developed by the injection of kidney nucleoproteids its administration causes an acute nephritis, which may be quickly fatal. In some cases 50 per cent. of the total nitrogen in the urine has been in the form of albumin.

A constant phenomenon was observed in what I have called the latent period. To illustrate: In some cases the nephrotoxin was given in small repeated doses intra-

peritoneally, and in others in one large dose intravenously. In the latter case the animal showed an immediate reaction, but in ten hours had completely recovered and remained normal for three to five days. At the end of this interval a slight amount of albumin appeared in the urine, and the condition grew rapidly worse, until by the eighth or tenth day the animal had a very severe nephritis. The few days which elapsed between the administration of the serum and the appearance of the albumin is the latent period.

Antisera made by the injection of nucleoproteids are not absolutely specific, for they have a weak hemolytic and hemagglutinative action. At such dilutions as are used *in vivo*, however, there is neither lysis or agglutination of the blood corpuscles. This statement is based on test-tube reactions, and it may be that the conclusions do not hold for the inoculation experiments. Without following the details of this work further, I may say that from it we have drawn the conclusion that it is possible by the injection of the pure nucleoproteids of a selected organ into the peritoneal cavity of an animal of alien species to develop a serum having a high degree of specificity in its action toward the selected organ.

At Dr. Rogers' suggestion I endeavored to apply the principles which had been determined in the work with hepatotoxin and nephrotoxin to the preparation of a serum which would have cytolytic action on the human thyroid gland and therefore be of therapeutic value in exophthalmic goiter. Just at this time we were fortunate in securing an autopsy the thyroid glands from two fatal cases of the disease, and it seemed best to make the first experiments with them. The problem is not precisely similar to that of the former work. We do not wish to produce a definite lesion in the gland or injure it to the same degree as we did the livers and kidneys. The ideal result would be an inhibition of glandular activity which would be sufficient to restore a more nearly normal condition of affairs. It seemed to me, also, that the problem was not simply one of producing a cytotoxin of some decided specificity for the thyroid, but that account must be taken of the fact that the thyroid secretion probably has toxic action, and we should endeavor to neutralize that as well as inhibit the gland. A brief consideration of the proteid constituents obtained from the thyroid will be necessary to understand how these two factors influence the work.

Three sorts of proteid may be obtained from a saline extract of the gland, viz.: nucleoprotein, globulin and albumin. The colloid matter contains globulin and albumin, while the nucleoprotein comes from the nuclei of the secreting cells. In the older literature the globulin was confused with the nucleoprotein. Oswald¹³ has shown in a number of researches that the globulin is the iodine-containing proteid of the gland and that it alone is responsible for the peculiar physiologic activity which the whole gland has. Accordingly we isolated in pure form the nucleoproteids and thyroglobulin from the Graves' glands at our disposal. The method of isolating the nucleoproteids was the same as that followed in the previous work with dog organs and has been described fully in the paper¹¹ already published. The globulin was precipitated by half-saturation with ammonium sulphate, and, after filtration and washing, the excess of salt was removed by dialysis. Some injections were made from the fresh proteids, but the larger portion was dried at low temperature for preservation. A mixture of the two proteids was injected into rabbits. The nucleoproteids were included in this mixture be-

cause I wished to produce some cytolytic effect on the thyroid gland, and the globulin because I hoped thereby to develop an antitoxin to counteract the toxic symptoms. We have been accustomed, therefore, to speak of our serum as having both cytolytic and antitoxic properties, but our only reasons for so speaking have been the theoretical ones just mentioned. It may be that a serum made from the globulin portion of the gland would have cytolytic action. Portis, however, did not find that his serum made from the colloid of the gland had much cytolytic effect. A serum made from the nucleoproteids alone may have antitoxic properties, but I should not expect such behavior, *a priori*, because the nucleoprotein is not the portion of the gland responsible for its toxic effects. I am certain, however, that the whole gland is not essential to the production of a potent serum, and it seems not unreasonable to conclude that the nucleoproteids are as intimately concerned in the production of thyrotoxin as they are of hepatotoxin and nephrotoxin.

The rabbits were given injections of the proteids intraperitoneally at five-day intervals and were bled on the eighth day after the last injection. The earlier serum was developed from larger quantities of proteid than the later, because our supply of proteid would not permit us to continue such liberal treatment as we had given at first. I believe these smaller injections did not produce so active a serum. The amount of proteid given at each injection varied somewhat with the size of the rabbit and his reaction to the treatment. During the first two weeks a six-pound rabbit would generally lose one pound in weight, but this was followed by a slow gain to nearly or quite the original condition. The animals were bled from the carotid artery into sterile tubes and the serum poured off after the clot had been allowed to contract for twenty-four hours in the refrigerator.

I believe that the results of the therapeutic application of the serum are more than coincidence and that an impartial consideration of the clinical evidence must lead to the conclusion that improvement and, in some instances, recovery has been caused by the administration of the serum. The physiology and pathology of the thyroid gland are so obscure that such a means of treatment as the employment of a cytolytic serum can not be applied as yet with a high degree of intelligence. There must be some degree of experimentation with each patient. An active antiserum made from human tissues is capable of doing a great deal of harm and must be applied with great caution. It can not be said of such a serum, as it often is of tetanus or diphtheria antitoxin, that it may be used in liberal quantities because it will do no harm even if it does no good. The therapeutic dose is a very small one. Alarming reactions have followed the injection of one cubic centimeter of the serum. I do not claim that the serum is absolutely specific. We have only the clinical evidence on this point backed by the analogy with the hepatotoxin and nephrotoxin, which is imperfect, because those were developed from nucleoprotein alone, while the thyrotoxin has come partly from the globulin injected. In fact, we have produced just enough light to intensify the darkness.

The work has suggested more questions than it has answered and, very naturally, we have now experiments in progress to determine whether a serum can be made from normal thyroids which will be efficient therapeutically. No definite statements can as yet be made in regard to the matter, for, in view of the lack of conclusive experimental evidence, personal opinion is of no consequence.

THE TREATMENT OF EXOPHTHALMIC GOITER BY A SPECIFIC SERUM.*

JOHN ROGERS, M.D.

Surgeon to Gouverneur Hospital, Assistant Surgeon to St. Francis Hospital.

NEW YORK.

The most generally accepted theory of the direct causation of the symptoms of exophthalmic goiter, or Graves' disease, is overactivity of the thyroid gland, and the active portion of its secretion is similarly believed to be a globulin containing iodine, called thyroglobulin. In the attempt to neutralize this secretion or check its production several schemes for serum or allied methods of treatment have been tried. Among these may be mentioned the serum of thyroidectomized dogs drawn after the animal had been operated on and had developed symptoms of athyroidism; the serum of a patient suffering from fully developed myxedema; the serum and the fresh and dried blood and the fresh and dried milk of the thyroidectomized goats, commonly known as Möbius serum; the serum of herbivorous animals which had been fed for varying lengths of time on the thyroid glands of animals of another species, and the serum of animals into which emulsions of the thyroid glands of another species had been injected. Conflicting results have been reported for all these, but they generally agree in a failure to cure.

While assisting last year on the clinical side of the work in some experiments for the production of cytotoxins, conducted by Dr. S. P. Beebe in the laboratories of the Cornell University Medical College, I was greatly impressed with the specific character of a nephrotoxin which he had made from dogs' kidneys. The principle seemed directly applicable to the treatment of exophthalmic goiter, and as I obtained at this time two of what are clinically and in the gross the large, soft, cellular thyroids of exophthalmic goiter, I induced Dr. Beebe to make from this material a thyroid cytotoxin for man in the same manner as he had already made the kidney cytotoxin for the dog. The glands were ground to a pulp, extracted with normal salt solution and the coarse fibers strained off. The rather thick, cloudy filtrate was then made frankly acid with acetic acid and a heavy precipitate of nucleoproteids resulted. The supernatant liquid was then syphoned off and half saturated with ammonium sulphate, which carried down the remaining nucleoproteids and the globulins including the thyroglobulin or supposed active secretion of the thyroid gland. These precipitates were combined, and after removing the neutral salt by dialysis were, to some extent, injected while fresh into rabbits. The major part of the precipitate was, however, dried for preservation. The rabbits showed a severe reaction to these injections and some died (one, at least, with many of the symptoms of exophthalmic goiter) and thus wasted our precious material, which at first was used freely. After about five weeks of this treatment the rabbits were bled to death from the carotid and the serum thus obtained from these first inoculations I shall call serum A.

Serum B was made in August from the dried precipitate, then four months old, of nucleoproteids and thyroglobulin obtained from these diseased glands. The powder was dissolved in normal salt solution and injected as before into rabbits, but the demand for the finished product was urgent and somewhat more haste was employed than in the preparation of serum A.

* Read at the New York Academy of Medicine.

The preparation of serum C in a similar manner was begun a month later, or when the dried powder was about five months old, and the animal inoculations were conducted with care and slowly, but with as little of the original material as would produce a reaction, since by this time its value was becoming apparent and the quantity of the dried precipitate very much decreased.

Serum D was made from the normal human thyroid gland as obtained at autopsy in the morgue, and has not proved satisfactory. The glands which have generally been received several days after death were ground to a pulp, extracted with normal salt solution and the liquid strained through gauze. The filtrate was then made acid with acetic acid and, as very little precipitate resulted, dilute alcohol was added. The precipitate thus finally obtained was suspended, while fresh, in normal salt solution and injected into rabbits at intervals of about five days for some four weeks. The animals showed little or no reaction to the treatment with this material, and thus presented a noticeable difference from the previous experience.

The results produced by these sera are best explained by a brief summary of the case histories:

A. F., suffering from typical exophthalmic goiter, received a total of 30 minims of serum A when it was fresh, and showed a pronounced local and constitutional reaction about four days after the first dose. Recovery took place gradually and the condition was practically normal at the end of some five months.

E. R., suffering from typical toxic exophthalmic goiter, received 15 minims of the fresh serum A at one dose, and had a bad cardiac dilatation five days later, but recovered completely during the next three or four months.

M. B., suffering from a severely toxic exophthalmic goiter, received 1 c.c. of the fresh serum B in divided doses with a pronounced reaction four days after the first dose, but has now (five months later) recovered from practically all symptoms.

A. P., suffering from a severely toxic form, also changed from a moribund to a convalescent condition within three days after the administration of 2 c.c. of serum B and 2 c.c. of serum C when each was about three months old. She seems now to have almost completely recovered. There was no bad reaction whatever.

E. M., with a typical form of the disease, showed a similar postponed reaction and slow recovery after a small initial dose of serum C when it was a few weeks old.

L. M., suffering from typical toxic exophthalmic goiter, received a similar dose of serum C when it was two months old, and, without any noticeable reaction, was changed from a moribund to a convalescent condition and has now completely recovered.

F. E., suffering from an atypical form of the disease, showed a severe postponed reaction to serum C when it was a few weeks old and then recovered gradually.

The other three cases showed the same peculiarity, but have not exhibited much or any improvement or reasons revealed in the case histories.

Thus ten cases have been treated with sera A, B and C, with a result of three apparently perfect cures, three rescued from a critical condition and now approaching a cure, and the others more or less improved, their improvement depending, as it now seems, on several factors which it is legitimate to attempt to explain. In this explanation, however, it must be borne in mind that a great deal is inference or supposition and very little has been definitely proved.

It was noted in these cases that the first serum made by freely inoculating the rabbits with the fresh precipitate of nucleoproteids and thyroglobulin of the diseased human gland produced the best results with the smallest

dose and the most reaction (serum A). The serum made later, when this precipitate from the diseased thyroid was several months old, was made in some haste and still proved effective, but required a larger dose and produced somewhat less reaction (serum B). The serum made still later (serum C) was derived from smaller injections of the dried precipitate carried over a slightly longer period and was about the same as serum B, but apparently less efficient than serum A. Each of these produced no appreciable result after injection until the lapse of at least twenty-four hours, and then there was some improvement in the subjective symptoms. Some four or five days after the first dose, and on the second or third repetition of the injection, there developed a severe erysipelatous erythema, with swelling all around the point of puncture. This would be intensified by another dose in a different part of the body and was accompanied by a sharp rise in temperature and very unpleasant cardiac disturbance in the form of irregularity or great rapidity and (in one case) sudden extreme bradycardia. The animals treated with the specific cytotoxin for the kidney, liver or pancreas would show little or no reaction for several days, perhaps a week, and then suddenly sicken and die, and at autopsy the organ under investigation would be found to be the one chiefly affected. The kidney and liver consist almost entirely of secreting cells, and so supply a large amount of definite material, presumably nucleated secreting cells, for which the inoculated animal can produce antibodies. The normal thyroid, on the other hand, contains a good deal of stroma, blood vessels and colloid, but comparatively few secreting cells, and to make a cytotoxin which is specific in a pronounced degree for any given kind of cell it seems to be necessary to use that kind of a cell for the inoculations, not only in considerable quantity, but as much as possible, to the exclusion of all other kinds of cells. Therefore, to make a cytotoxin for the thyroid gland there must be obtained, in the first place, a great number of the secreting cells of this organ, and then as few as possible of the cells of the stroma and blood vessels which are common to all other organs and tissues.

Whether this is true or not, the precipitate or nucleoproteids obtained from the ground-up Graves' thyroid, suspended in salt solution, is very abundant and comes down in a flocculent mass, while the similar precipitate from the normal gland is almost inappreciable and has to be obtained by a slightly different method. The supernatant liquid over the first heavy precipitate from the Graves thyroids contains, as stated previously, some suspended nucleoproteids, and with them the globulins, including the thyroglobulin or supposed active secretion of the organ. These were precipitated separately by ammonium sulphate and then combined with the first precipitate of nucleoproteids by acetic acid, and after removing the neutral salt, injected into rabbits at intervals of five days for four weeks. There were thus produced antibodies for both the cells and their secretion; in other words, a serum which may be supposed to contain both a cytotoxin and an antitoxin. These terms are used only as conveniences in an attempt to construct a working hypothesis, and it must be remembered that the difference between a cytotoxin and an antitoxin is by no means clearly understood.

In the experiments with a cytotoxin designed to be specific for a dog's kidney, the animal showed no reaction for several days and then died from an acute nephritis. The severe reaction with the thyroid serum in the patients whose histories are given took place after a corresponding interval succeeding the first dose if the

serum was fresh, but if it were old the reaction seemed to decrease in proportion to the age of the serum. At the same time the permanence of the effectiveness of the dose also seemed to decrease, and hence the bad qualities of the medicament can not be eliminated by storing it in an icebox for several weeks or months. The bacterial cytotoxins have somewhat the same perishable characteristics.

But there is also some appreciable improvement, especially in the nervousness and sleeplessness which takes place within a few hours of the time of administration of this serum, and this property still persists apparently as strong as ever in some of serum B, now five months old, and as the thyreoglobulin was contained in the material originally used for inoculating the rabbit it is reasonable to imagine an antibody for it, or an antitoxin, in the serum. This also is comparable with the bacterial antitoxins, which persist unchanged for a long period and when administered act quickly.

If this double content of the serum can be granted, the one for lack of a better term called a cytotoxin, having a late and cumulative effect in suppressing the action of the thyroid secreting cells, and the other, an antitoxin nullifying the action of the excessive thyreoglobulin, much helpful light is shed on the clinical phenomena. We may imagine, and it is not incompatible with the clinical facts, that the fresh serum stops the active poisoning and a little later inhibits the activity of the gland, and in doing so in some manner breaks a vicious circle which, without destroying the thyroid, leads to a gradual resumption of its normal function. If, however, the serum is old or deficient in the supposed cytotoxin element, there is only a temporary suppression of the pathologic process, which in course of time is again in evidence.

The above statements summarize our present knowledge of and experience with this remarkable serum, and are admittedly very incomplete and unsatisfactory. It requires weeks to prepare the serum and months to observe its effect, and as the subjects all have to be human and the medicament is evidently dangerous its administration has to be conducted very carefully and slowly. Any error in the preparation, or any bacterial contamination, means a "start all over again," but we have always kept a little of the original very effective material on hand to use in critical cases. The ordinary treatment, fortunately, can carry along the average case until we are sufficiently sure of any particular product that happens to be ready. I have purposely omitted all mention of the etiology, pathology and symptomatology of exophthalmic goiter, as this involves another uncertainty in that some forms of the disease may not be amenable to this treatment. In fact, I do not believe that a serum made by this method will cure all cases of the disease, as there have been very marked differences in the individual reactions. As a general rule, although it is not invariable, those who have had the most reaction have progressed the most satisfactorily, and it does not seem to hasten recovery if the injections are constantly pushed. On the contrary, this seems to retard the progress.

Then there is a certain type of cases which has seemed peculiarly refractory and liable to relapse. These patients have no exophthalmos, but they do have an asymmetrical thyroid, that is, one with a cystic or adenomatous enlargement. They complain chiefly of digestive disturbance, with fermentation and pain, which may be abdominal or thoracic, and with this disturbance there is generally dyspnea and labored breathing. They also have marked weakness, a soft, feeble pulse, and either

an intermittent or constant tachycardia. They are emotional and generally "nervous." Operative removal of the adenoma or cystoma is usually futile in that it does not cure the symptoms, and the interference may be dangerous, as I have more than once observed.

The bad chronic cases of the disease, with dilated and hypertrophied heart and the secondary lesions following imperfect circulation, should, of course, recover much more slowly than those which are uncomplicated or of less duration. I believe that when the thyroid is removed by operation for exophthalmic goiter and an acute thyroïdism follows, it can be checked by serum C, and I have preserved some of it for this purpose, but have not yet had the opportunity of thus testing it.

The difficulty of obtaining the normal human thyroids in a sufficiently fresh and uncontaminated condition (to say nothing of the pathologic thyroids) and the technical difficulties in the manufacture will probably prevent any commercial use of the product. The least error or variation in the complex mechanical or chemical methods employed by Dr. Beebe may spoil the finished serum or make it extremely dangerous, as I have more than once verified. A very skillful chemist, experienced in biologic work, is a necessity.

I can only say in closing that typical exophthalmic goiter has been cured by serums A, B and C, and this experience can be repeated with a serum made and administered in the same way; and if it ultimately proves to be necessary for some poor patient to die or to be operated on to obtain the pathologic thyroids of exophthalmic goiter in order that others may be saved it would indeed be a scientifically grim romance.

CASE 1.—History.—A. F., 27 years old, single, saleswoman, had always been nervous and excitable, and as a child remembers "hearing in her ears," the peculiar buzz or whir synchronous with the pulse which so many of these patients find annoying. She first noticed "palpitation" and dyspnea on exertion and attacks of diarrhea and shortly afterward, or when about at the age of 24, she observed the goiter and exophthalmos.

Examination.—When I first saw her in May, 1903, she had all the typical signs of the disease with a soft symmetrically enlarged thyroid, moderate exophthalmos, rapid respiration, which became dyspnea on exertion, marked pulsation of the great cervical vessels and a soft compressible pulse of 120 to 130. Her last physician had been giving her small doses of a dried thyroid preparation, which she thought made her feel a little stronger. This was stopped and small doses of potassium iodid for several weeks gave perceptible though temporary benefit to the tachycardia. When this medication had lost its effect, she received thyroidectomized goat serum by mouth, capsules of dried blood of the goat, "Iddymint," bromid of quinin, aconite, belladonna and many other usual and unusual medicaments, without benefit. In the winter of 1904-05 she began to lose ground and could work only a portion of each month. She finally weighed about 90 pounds and complained constantly of the heaving heart action, sleeplessness, dyspnea and weakness. There were also all the usual symptoms, with a large soft thyroid and pronounced exophthalmos and pulse of 120. She was able to walk, though with difficulty.

Treatment.—April 15, 17 and 19 she received first 5 then 10 and next 15 minims of serum A. April 17 she said the palpitation and sleeplessness during the previous night had been much improved, but there was no other noticeable change except some erythema in the right arm about the point of inoculation. After the injection in the other arm on the 19th, this erythema became much intensified and a much worse one developed around the last injection and suggested a saturation of the system with the serum. There was some fever, and she felt sick enough to go to bed. This passed in a few days, and at the end of a week there was a decided improvement.

The heaving heart action, the carotid pulsation, the sleeplessness and most of the nervousness had disappeared, and though the pulse was still about 120, it was of much better quality. At the end of another week she had gained about 10 pounds in weight and resumed her work of standing daily behind a counter.

Result.—There was a steady though not very rapid gain, which was hastened greatly by a residence at the seaside during August, and on her return the exophthalmos had entirely vanished, but a slight goiter even now can be felt, though not seen. She says that she can note by the size of her collars that each month, since the change began last spring, the neck has decreased in circumference, and at present it is as it was when she considered herself well. She now has a good figure, and looks and apparently is perfectly healthy.

CASE 2.—History.—E. R., aged 37, married, showed the first signs of the disease in the form of goiter, exophthalmos and tachycardia about twelve years ago. Every conceivable treatment was tried without more than temporary improvement. During these years she bore two children to full term, and during gestation the disease was scarcely noticeable, but after the birth of each child it returned within a few weeks and caused much disability. She received the thyroidectomized goat serum, the dried blood and the milk without the least benefit. Iodid of potassium in small dosage had at one time some temporary effect in slowing the pulse. Year by year the disease was very slowly but steadily becoming worse. In the spring of 1904 a bad anemia developed, which was relieved somewhat during the summer, but recurred after the winter of 1905, and in April the pulse ranged between 130 and 150 and the patient had to spend most of the time in bed. The hemoglobin was at this time 46 per cent., and the red cells 3,600,000. The exophthalmos was pronounced, and there was a large soft goiter.

Treatment.—April 25 she received 15 minims of serum A hypodermatically. As she was only my second case and in a serious condition, I fortunately awaited developments. April 30 there was a sudden attack of faintness, followed by labored breathing and dyspnea, and the heart became very irregular and apparently dilated. The pulse an hour or two later ranged between 30 and 40 to the minute, and not for another day did it rise above 40. There was nausea and some diarrhea. With careful nursing and without any medication except a little strophanthus and iron, the condition very gradually improved, and a month later she was moved to the country, where she soon became able to walk.

Result.—The "nervousness," dyspnea, sleeplessness and tachycardia reappeared at intervals during the summer, but the intervals grew longer and finally all symptoms vanished about September. The goiter, however, subsided very gradually, and at about the menstrual periods evidently enlarged a little temporarily, but each month was less perceptible and disappeared in August, but could be palpated as late as November. The exophthalmos was not noticed after August or September, and she is now a perfectly normal woman.

CASE 3.—History.—McQ., 37 years of age, widow, cigarette maker, has had a typical form of the disease for nine years and dated the outset from the death of one of her children. For the past winter she has been able to work at her trade only about three days a week, and she became so weak and short of breath she could with difficulty reach the dispensary. The pulse was about 130 when she was quiet, there was pronounced exophthalmos and a large firm goiter.

Treatment.—May 8, 10 and 12 she received first 5 then 7 and next 10 minims of serum A, which was not well preserved. On the 8th there was some erythema and on the 12th it was pronounced, but no perceptible improvement was noted. She disappeared and was forgotten until she came back in November in much the same condition as when first seen, but with a remarkable story. She said that after the last dose on May 10 she had been very ill with a "sore arm and heart trouble," and had been confined to bed for about two weeks; apparently a bad erythema with fever, but with no suppuration. The heart trouble seemed to have been something like a dilatation, as there had been faintness and irregular "thumping" with dyspnea and nausea. This subsided and she worked

steadily at her trade all that summer. The exophthalmos and goiter had been less noticeable, but had now recurred with the dyspnea, tachycardia and weakness. The pulse was 120 in November.

November 10, 13 and 17 she received 1 c.c. of serum C, then about two months old. On the 17th a rather severe erythema followed, and for a few days she had to stay in bed for weakness, but on the 20th she resumed work. She began to feel stronger, but the physical signs remained, and during December I tried serum D, made from the normal gland by a slightly different process. Three rabbits were employed, each inoculated in the same way, but the serum from each, while giving the same general effect, varied perceptibly in the severity of the resulting symptoms. Within one or two days after the injection the pulse would rise 15 to 20 beats a minute and be accompanied by a heaving heart action perceptible under the clothing. At the same time there was some swelling of the arm, but very little erythema. The exophthalmos was increased and the general nervousness, tremor and weakness was generally intensified. In the course of four or five days these symptoms would subside, and she would feel better than before and raise my hopes and her own. But the pulse remained about 120 or a little more, and this caused me to try another rabbit; No. 320 seemed a little worse than No. 311, but both were bad, and therefore on December 29 I gave 1 c.c. of serum D from No. 68. December 31 there was considerable swelling and some erythema about the point of injection. January 1, I was asked to go to her house, and found her semiconscious, with a severe headache, pulse of 150 and somewhat irregular, with a heaving heart action and very bad exophthalmos. She was so weak she could scarcely move, and altogether the symptoms looked very serious. But the following day the condition improved, and on January 3 she was able to be out of bed. Evidently, serum D was decidedly dangerous, and produced a stimulating rather than inhibitive effect on the thyroid, and though this was noted after the administration of serum D from rabbits No. 68 and No. 311, the latter had subsequently seemed to produce some benefit at least in the subjective symptoms. No. 320, however, showed none of these feelings of betterment, and the condition which had been perceptibly improved by serum C during the middle of November had become again as bad as ever or worse.

Result.—She is still under treatment, and though the physical signs of the disease are not appreciably altered, she says she feels stronger and is able to work every day.

CASE 4.—History.—M. B., aged 26, single, trained nurse, had suffered from typical exophthalmic goiter for several years, but had been able to do her work. In May, 1905, she was compelled to go to bed, and in July she began to suffer from cardiac dilatation, irregular temperature, nausea, vomiting and diarrhea.

Examination.—I first saw her August 10. She was deeply pigmented, extremely emaciated and too weak to move unassisted. The exophthalmos and the firm goiter were not extreme, the breathing was labored and about 35 to the minute, the pulse was characteristic, the apex beat was in the left axillary line, there was a very plain precordial heave with each systole, and diarrhea and vomiting were very distressing. She had made all funeral arrangements, and only consented to see me on a friend's solicitation. As we had no serum ready at this time, I supplied her with some thyroidectomized sheep serum, and I think this kept her alive until serum B had been prepared, as the diarrhea and vomiting began to decrease, the respirations became a trifle less frequent and the pulse was better. Improvement was slight.

Treatment.—September 11, 13, 15 and 17 she received 1 c.c. of serum B, and on the 15th there was a severe erythematous swelling of the arm and a temperature of 103.4 F., which seems to have been made a little worse by the injection on the 17th. A marked improvement in the general condition began about this time. There were no more dyspnea, diarrhea or vomiting after the 12th, and on the 19th she was able to get out of bed for the first time since early in June. She began to walk about October 1, which was imprudent with the badly dilated heart. The pulse, though vastly better in quality, remained about 120. The goiter showed little or no

change, but the exophthalmos had nearly disappeared, and the pigmentation of the skin was fading.

October 12, 14, 16, 18 and 20 she received 1 c.c. of serum C, to hasten recovery. There was no reaction except some transient erythema, and a slight improvement in the pulse from 120 to 115, and afterward the appetite and the weight increased. October 28 1 c.c. of serum C was administered and 2 c.c. November 3 and 13 without appreciable reaction. After November 1 she began to gain a little more rapidly in strength and weight.

Result.—From September 11, when the first of serum B was administered, there has been steady improvement, until now she is able to do ordinary work without difficulty. The goiter within the last month has grown smaller more rapidly than during the previous months and has now, together with the exophthalmos, entirely disappeared, and though still a little weak, I think this patient can be honestly called cured.

CASE 5.—History.—E. M., aged 35, single, German dress-maker, has had typical exophthalmic goiter for about ten years. Three years ago she was forced to spend nearly the whole winter in the German Hospital, and seems at that time to have had severe symptoms, especially cardiac. She was afterward much improved, but for the past year has been able to work only at intervals.

Examination.—Her mental condition might be described as "unbalanced." There was only a very slight exophthalmos, a moderate goiter with a small cyst in the isthmus, but marked tremulousness and weakness. The pulse was between 120 and 140, soft and compressible, and there was a pronounced precordial heave.

Treatment.—September 21, 22 and 25 she received first 10 then 15 and next 20 minims of serum B without any result until September 26. Then a severe erythema developed around the point of last injection, and was accompanied by some fever and an irregular and very feeble pulse. She became unable to walk, and was sent to St. Francis Hospital, where the hemoglobin was found to be 73 per cent. and the red cells 3,700,000. With rest in bed, some improvement was noted. She received 1 c.c. of serum C October 5, 8, 10, 12, 18 and 23, without any noticeable reaction, and with a slow and very intermittent gain. October 16 the hemoglobin had risen to 82 and thereafter progress was more satisfactory. She left the hospital October 26 with a pulse of about 80, but the goiter had only decreased very slightly. During the next menstruation there was a recrudescence of all symptoms, but they subsided at its close, and since then she has been more or less steadily gaining. At constantly longer intervals there have been attacks of tachycardia and breathlessness lasting for a few hours or a day after any of the nervous strain inseparable from her trade, which involves fitting clothes on occasionally irascible customers. After one of these occasions in December she came to me very angry and with a pulse of 150, and complaining that she had been unable to sleep the previous night from worry. I gave her 1 c.c. of serum C, and a week later she reported that she had slept perfectly ever since, and I found the pulse after a quick walk 78.

Result.—At present she eats and sleeps well, has no exophthalmos and no goiter, except the small cyst which can be felt but not seen, and no tachycardia, though the pulse ranges between 80 and 90. But she is irascible, and I think slightly "unbalanced" in mind, and small incidents seem to send it up above 100. Nevertheless, I think she can be called well physically.

CASE 6.—History.—L. M., aged 25, single, Russian, entered Gouverneur Hospital Sept. 25, 1905, with a history of weakness, palpitation and dyspnea for the past five or six years. She had been able to be about until within a week or two. Then there had been an exacerbation of all symptoms and she came to the hospital with a temperature of 101, and a pulse ranging between 120 and 140. She became gradually worse.

Examination.—I first saw her October 27. The temperature was then 102, the pulse 148 and the respiration 44 and very labored. The heart was evidently dilated and hypertrophied, and there was a precordial heave with each systole over the whole front of the thorax. The exophthalmos was pronounced and there was a considerable but not excessively large, sym-

metrical firm goiter. There was marked pulsation of the cervical vessels. The dry tongue of toxemia with constant nausea, diarrhea and extreme emaciation and weakness completed the picture of the critical condition.

Treatment.—October 27, 29, 31 and November 2 she received hypodermatic doses of 1 c.c. each of serum C, then nearly three months old, without any had reaction except a considerable local erythema. Within twenty-four hours of the first dose the nurse noted a cessation of the nausea and diarrhea, and on the following day the heaving respiration and heart action was evidently less and November 5 the pulse was 110 to the minute for the first time since September 28. There was only a gradual improvement, more evident in the general characteristics of the disease than in the recorded pulse and respiration. Temperature reached normal November 4. November 7 and 14 1 c.c. of serum C was given. On the days following these injections there was considerable local erythema and a rise of temperature to 102, but after November 20 it remained practically normal. She had then received in doses of 1 c.c. each a total of 6 c.c. of serum C, and on November 23 all the symptoms except a slight goiter had practically disappeared, and the patient had a ravenous appetite and was beginning to be out of bed a few hours daily. Everything pointed toward a complete though slow recovery, but November 24, 26 and 28 each I gave her 1 c.c. of serum D from rabbit No. 311. The first dose was followed on the next day by a bad erythema, a temperature of 104 F., pulse of 136 and a respiration of 44. This subsided within another twenty-four hours, and the next two doses only produced a transient disturbance, but though the general condition, the appetite and the digestion remained good, the pulse continued in the neighborhood of 120 and the precordial systolic heave began to reappear. Therefore, December 6, 8, 10 and 11 each she received 1 c.c. of serum D from rabbit No. 320, without any noticeable change one way, or the other. December 22, 23, 24 and 25 she received of serum D from rabbit No. 68, 0.5 c.c., 1 c.c., 1.5 c.c. and then 2 c.c. Within half an hour of the last dose she became flushed and showed an evident swelling of the thyroid, protrusion of the eyeballs very exaggerated and irregular heart action and great dyspnea. This was apparently an acute thyroidism and her condition looked alarming. But the next morning this had subsided, although she remained weak and nervous for several days and did not regain her improvement until I began the administration of another serum, which will form the basis of a future report.

Result.—At present (January 17), under the new medication, she seems to have regained the ground lost by this faulty serum D, and the pulse is again between 110 and 120.

This is a somewhat remarkable instance of the extreme complexity of these sera, as only by such experiences did I realize the necessity of adhering exactly to the formula used in the preparation of serum A. Serum D was made from the normal human thyroid, but by a process which differed from the first in an almost inappreciable degree.

CASE 7.—History.—A. P., aged 29, single, Swedish domestic, entered the Presbyterian Hospital under the care of Dr. W. G. Thompson Dec. 11, 1905.

Examination.—She had a temperature of 102, pulse of 120, and respiration of 25 to the minute. There was a slight but perfectly plain, soft symmetrical goiter, precordial heave, marked pulsation in the cervical vessels and evident dyspnea, but no exophthalmos. She was very weak and tremulous, and had some nausea and diarrhea. She gave a history chiefly of this and "nervousness" and sleeplessness for only the past two weeks, and had therefore an acute type of the disease. The condition grew rapidly worse, and December 16 the temperature was 104, the pulse 136 and the respirations 36; the tongue was dry and hard, there were ecchymotic spots in various parts of the body and evident thrombosis in some of the veins of both legs. The picture was one of a severe and probably fatal toxemia.

Treatment.—December 16 and 17 she received 1 c.c. of serum C and on the 20th 2 c.c. of serum B and no other

medication then or afterward. There was no appreciable reaction and after the second dose there was a very marked improvement in all the symptoms. December 22 the temperature, pulse and respiration were practically normal.

Result.—Since then there has been a steady though rather slow progress toward recovery. She is up and around the ward at present with no signs of the disease, except weakness, some anorexia and a soft thyroid which can be felt, but is not perceptible to sight.

This patient has rather upset my calculations, as, judging from other experiences (in chronic cases), she ought to relapse on account of the supposed absence of the cytotoxin in the serum she received. It may prove that only the antitoxin element is needed to cure these severe acute cases, as at present she is progressing very satisfactorily.

CASE 8.—History.—F. L., aged 50, single, has always been a "nervous" woman, but ascribes the beginning of her illness to the nursing of a relative, who later died. Soon after this, in 1888, she noted an enlarged thyroid and had dyspnea and tachycardia on exertion. The symptoms continued and she became an invalid. The tachycardia only came on at intervals after exertion or excitement or sometimes spontaneously, and lasted from an hour or two up to several weeks. When in good condition physically and mentally it was not troublesome. The physical weakness was always present.

Examination.—I first saw her in October, 1905, and thought she had an atypical form of the disease. She was stout, and had a large median cyst of the thyroid with some palpable but soft enlargement of the lateral lobes. There was exophthalmos, and in repose or after resting the pulse was 75 to 80 to the minute, and was soft and compressible. But after exertion or excitement the pulse beats would increase to 120 or 140 to the minute, with dyspnea and a general cutaneous "flushing." She could with great difficulty walk up one flight of stairs. There was also sleeplessness, poor appetite, fermentation, eructation of gas and frequent attacks of diarrhea.

Treatment.—October 6, 8, 10, 12 and 16 she received 1 c.c. of serum C. On the last date a severe erythema developed and prostration, irregular heart action and some fever (101 F.). She then began to improve and lose flesh. Improvement was not constant, as dyspnea and faintness with a feeble but not rapid pulse occurred from time to time. These attacks have decreased gradually in severity and frequency, and now are rare.

Result.—She now has a good appetite and feels reasonably strong, and at least goes about as any one else, and is what I call well. The cyst of the thyroid is present, but the lobes are not visible, and are not palpable except close to the cyst. The pulse is of excellent quality and not soft and compressible, and averages about 80 to the minute.

The history of this case is that of a type of cases in which there are only a few of the symptoms and in which this treatment ought to be helpful. Generally there is no exophthalmos, but an unevenly enlarged cystic adenomatous thyroid. The chief complaint of the patients is concerning gastric or intestinal indigestion, fermentation, abdominal or thoracic pain, often with dyspnea or labored breathing. There is also extreme weakness, occasional, frequent or constant tachycardia and a weak and compressible pulse.

CASE 9.—History.—M. R., aged 25, married, had been ill for about a year with typical exophthalmic goiter of moderate severity.

Examination.—There were all the usual signs. The pulse at my visit was 140 to 150, ordinarily it was about 120, soft and compressible.

Treatment.—She received November 7 and 9 1 c.c. of serum C, then about two months old. At the end of a week her pulse was about 80 and of good quality, and all the subjective symptoms were greatly improved, but there had been no marked change in the goiter and exophthalmos.

Result.—She received no treatment after this, and lately I have been informed that she is about the same as when I saw her on November 7, but that there has been much less "nervousness."

This was not a fair test, but is included with the others who received sera A, B and C.

In no instance did suppurative develop after any of the injections in these cases.

CASE 10.—History.—A. S., aged 23, single, stenographer, was a champion basket-ball player and an all-around athlete. She dates the beginning of her symptoms to a period of prolonged exertion and grief in 1899.

Examination.—I first saw her Nov. 11, 1905. There was pronounced exophthalmos. The thyroid was symmetrically and very much enlarged, and her thin neck measured 14½ inches over the goiter. She was much emaciated, showed a very marked pulsation in the cervical vessels, including the veins, which were prominent, and had a precordial heave over the whole left thorax. The diffuse apex beat was 12.5 cm. to the left of the median line. There was also marked dyspnea on exertion or excitement. The pulse varied from 120 to 140, and was soft and compressible.

Treatment.—November 11, 15, 17 and 21 she received 1 c.c. of serum C. November 19 her temperature rose to 102, there was a severe erythema in both arms, but mostly about the point of the last injection, and she felt sick and very weak, though the pulse was about the same (120). November 21 these symptoms had subsided, and she began to menstruate. It is worth recording that the exophthalmos, goiter and nervousness during this period, lasting two days, were all marked, but the pulse had come down to 104, the lowest for many months. The next day, November 22, it was very irregular. November 26 considerable improvement was observed. The neck measured an inch less in circumference, the thyroid was softer and the protrusion of the eyes was less marked, but to hasten recovery I gave on this day and again on November 29 1 c.c. of serum D from rabbit No. 311. Shortly after the last dose there occurred an acute exacerbation of all the symptoms, with protrusion of the eyeballs, swelling of the goiter, dyspnea and a feeling of suffocation and then vomiting and diarrhea. For a few hours the pulse was about 160. On the following day these disagreeable symptoms had subsided, and though she complained much of sleeplessness, the pulse became slower, and from December 2 to 6 did not go much above 90. December 10 some diarrhea had appeared, and I gave 0.5 c.c. of serum D from rabbit No. 320, which seemed to stop it. December 12 she received 2 c.c. of serum D from rabbit No. 320, and within an hour or two went into collapse, and her physician, who was hastily summoned, described the symptoms as those of an acutely exaggerated exophthalmic goiter. The eyeballs protruded so that the lids could not be closed at all, the thyroid was swollen, there was an alternating syncope and extreme restlessness, with an irregular and uncountable pulse, vomiting and later diarrhea. With diffusible stimulants this condition gradually subsided, and the next morning all the signs were about as they were when she was first seen November 11.

Result.—She did not care to repeat this experience, but since then she has shown considerable improvement, much to my surprise, as I thought I had undone with serum D all that had been gained with serum C.

The Physician's Personality.—In dealing with sick men, remarks *American Medicine*, the personal equation of the invalid is the thing to study. It is really as important to know "what kind of man the disease has got as to know what kind of disease the man has got," so that what seems to be trickery is merely winning confidence, on which many an invalid starts to recover at once. It's the kiss on the baby's bruise—satisfying and curative. After all, most of us only want a little sympathy when we are sick, and, like big babies, we pine if we don't get it. Patients pay well for it, and the successful doctor dispenses it with his drugs, while the learned fool, who hasn't any sympathy to spare, is a flat failure, though his treatment in other ways may be therapeutic perfection.

SURGICAL TREATMENT OF GOITER.*

ROBERT WALLACE HARDON, M.D.

Attending Surgeon Cook County Hospital and Drexel Sanitarium;

Attending Orthopedic Surgeon Post-Graduate Hospital;

Member American Academy of Medicine, etc.

CHICAGO.

PATHOLOGY.

For a proper understanding of the subject it is necessary to give a short review of the various pathologic conditions which affect the thyroid gland, together with a brief description of the clinical pictures presented by each.

Normally, the thyroid gland, a ductless body, is composed of a vascular stroma supporting acini which are lined with a single layer of epithelial cells. The acini contain colloid material which keeps the epithelial cells from contact.

Simple Goiter.—In simple goiter there is found only increased colloid material, causing greater distention of the acini.

Exophthalmic Goiter.—In this variety we not only find a greater amount of colloid material, but an increase of the epithelial cells causing an irregular invagination of the lining of the acini. These two varieties may be considered hypertrophies, as they represent normal thyroid conditions exaggerated. Both of these varieties show a fairly symmetrical enlargement of gradual growth.

In simple goiter the time of onset is usually between the ages of fifteen and thirty years. Primarily, it may be associated with nervous symptoms, tachycardia, palpitation and tremor, increasing for a time, but which later may subside without treatment. There is no exophthalmos.

There has been frequently noted an enlargement of the thyroid gland dating from the early menstrual period, which enlargement in some cases has disappeared without treatment before the thirtieth year. The hypertrophy may by pressure cause dyspnea, difficulty in swallowing, cough and occasionally bloody expectoration, but it should be noted that the latter are all late symptoms.

In exophthalmic goiter the age of onset is usually between twenty and thirty years. The most prominent clinical symptoms are intensified arterial pulsation, usually low blood pressure, palpitation, tachycardia, tremor, breathlessness on slight exertion and nervousness. Later the exophthalmos develops.

The other pathologic conditions of the thyroid nearly always cause tumors of irregular shape.

Acute Suppurative Thyroiditis.—L. L. McArthur says this is generally bilateral, usually following septic processes, as typhoid, puerperal fever or pneumonia. He names as symptoms sudden onset, rapid increase in size of neck, pain on motion of head, tenderness on palpation. Pressure on veins and nerves may cause a moist intense headache, hoarseness, dysphagia and even cyanosis of head and face. He mentioned as peculiar symptoms, great thirst, because of difficulty in swallowing; occasional severe epistaxis from pressure interfering with venous return, nausea, vomiting from pneumogastric pressure, hoarseness, vocal cord paralysis and dyspnea.

He advocates incision and drainage, with later enucleation of cyst, if continued suppuration. When situated beneath sternum, enucleation primarily, if the patient's condition permits, as in this locality drainage is not a safe practice.

In early fetal life the gland contains no colloid material, and the acini are filled with epithelial cells. Tumors resembling such fetal glands are named fetal adenomata.

The above and glandular adenomata, in themselves benign tumors are unlike benign tumors elsewhere, in that they are often followed by metastases, most frequently of the bones and the lungs, in the order named.

Carcinoma, sarcoma and mixed adenomata are not uncommon. If early in the enlargement bloody expectoration, painful swallowing or vocal symptoms are noted, carcinoma should be suspected. If one waits until a clinical diagnosis is possible metastases will have taken place, which will make operative interference of little avail.

Thyroid Cysts.—These may develop at any time from childhood to old age. They may be single or multiple. Bloodgood states that if an asymmetrical tumor has been present three years, and is confined to the thyroid gland, it is probably either a benign cyst, adenoma or adenocarcinoma in an operable stage.

Cysts are usually slow of growth, but may at any time grow rapidly. They may also vary in size from time to time. There seems to be no relation regarding these growths in the female to puberty or to pregnancy or the menopause.

Clinically, some of the patients exhibit no symptoms except the deformity caused by the growth. While others have atypical symptoms of exophthalmic goiter, which often disappear after the removal of the cyst, as in Case 2. They may cause annoying pressure symptoms.

In a series of cases of this class subjected to operative treatment at the Johns Hopkins Hospital there were no serious postoperative complications or mortality.

In considering the surgical treatment of goiter it should be remembered that the vast majority of cases coming to the surgeon have had the benefit of medical or electrical treatment, or both, for a greater or less length of time, and not receiving the relief desired, or growing more uncomfortable, come for advice and treatment. The foregoing leaves practically only the colloid variety to be considered. The class of cases which come to the surgeon bear a striking similarity to the class of cases of appendicitis which he saw but a few years ago, when the patient, neglected, was allowed to pass on from a condition in which there was but a fraction of a percentage of mortality to one where the percentage was great. In reviewing the literature in which cases have been reported in the last five years one can not help being impressed with the above fact. Mayo reports 128 operations, with eight deaths. Eliminating one cancerous and two "who should not have been operated on, as their condition was so aggravated as to almost class them as moribund previously to operation," the mortality rate is low for a class of cases, most of which had been given up after treatment by internists, since the process could not be made to recede, could not be checked, and did in the large majority increase in danger to and loss of virility of the patients. The deaths in cases of Curtis, Kocher, Witherspoon and others all show alike the increased mortality from this same cause.

Mayo further states: "During the past year two such cases were seen with regard to the advisability of operation, but with a knowledge born of bitter experience both were refused. One died in a week, the other lived a few weeks; both deaths were medical." Do we wait until the belly is full of pus and the patient nearly moribund before advising operation for the removal of an ap-

* Read before Fox River Medical Society.

pendix? Should the advising physician any more stand by and see death spreading out its arms by refusing a patient surgical aid when other measures have shown themselves to be of no avail?

OPERATIVE METHODS.

1. Injection is by many considered as dangerous as any of the other methods.

2. Ligation of the thyroid arteries is as dangerous as removal of the gland, except that in some cases it may take less time than an extirpation.

3. Resection of sympathetic ganglion. Jonnesco reports fourteen cases of bilateral sympathetomy, with no deaths. He resects all cervical and the first thoracic ganglions and believes it to be the operation of election in primary exophthalmic goiter. However, in exophthalmic goiter of long standing he would first do a partial thyroidectomy, and if improvement is not noted in a reasonable time, sympathetomy. Curtis reports three deaths in eleven cases. He says that this method gives good results, but sufficient time has not elapsed to show their permanency. There are many who believe that the destruction of the efferent lymphatics by this method accounts in a large measure for the improvement.

Improvement from the x-rays probably acts to some extent in the same way, according to Mayo and Murphy. Mayo frequently uses it in conjunction with other treatment from two to six weeks previous to operation.

Thyroidectomy.—Kocher reports four deaths in fifty-nine cases of thyroidectomy or ligation of the arteries. Witherspoon, nine cases, with one death. He says it is an operation which gives the greatest satisfaction and removes the lobe most affected, usually the right. Improvement is noted almost at once. Curtis reports seven cases, with two deaths. Mayo, before noted, reports 128 cases, with eight deaths.

A certain percentage of cases suffer from acute thyroidism following this operation, due in part to trauma of the remaining portion of the gland, its subsequent weeping into the wound and absorption. In May of this year the Mayos were practicing cauterization with Harrington's solution to reduce this effect.

The Kocher collar incision gives the best opening, with the least resulting disfiguration, and extends across the neck, if necessary, to the external border of the sterno-mastoid muscle. If necessary, this muscle can be cut, to be sutured later; so with the sterno-hyoid and thyroid muscles. In dissecting it is best to try to keep just inside the capsule. This will usually be found to be very thin anteriorly, and laterally, but thicker posteriorly. Bleeding points are caught with forceps or tied until the gland is separated, first superiorly the superior thyroid artery and vein being located, double tied and cut between. In dissecting below on the right side one must use care not to injure the recurrent laryngeal nerve, which lies in intimate connection with the inferior thyroid artery. This danger is avoided if dissection is confined to the inner side of the capsule. The lobe dissected off, the isthmus and a part of the opposite lobe may be removed if necessary. The preservation of capsular tissue at the stump end, so that the stump may be covered in, and the removal of any loose lobules, is a point in the technic which goes far toward reducing the tendency to acute thyroidism. The wound, clean and dry, is closed except for an opening left for drainage. After operation the patient should be given salt solution subcutaneously, and this should be repeated at suitable intervals, if the patient has lost much blood or is anemic, to prevent absorption from the wound.

Should thyroidism occur, suprarenal extract given in small repeated doses and atropin and morphin give the most satisfaction.

Just a word as to anesthetics. Local anesthesia has an advantage in that the patient tells at once if the recurrent laryngeal nerve is caught, and can be used in all cases where a general anesthetic is contraindicated.

If, previous to operation, morphin is given, light general anesthesia is safe in the majority of cases suitable for operation.

I have never seen scopolamin used in this class of cases nor have I found any reports of its use.

The results of all operators are practically the same. Marked improvement in from 40 to 60 per cent. of cases almost at once, and in nearly all of the rest in a few months following operation. In exophthalmic cases the exophthalmos is the last symptom to disappear.

CASE 1.—Mrs. S. W., aged 39; two children; born in Sweden; came to United States at age of 17 years; housewife.

History.—First noticed enlargement of neck twelve years ago, which had gradually increased in size up to two years ago, when it grew more rapidly, attaining such size as to cause marked deformity, hoarseness and at times difficulty in swallowing. During the three weeks previous to operation the pulse averaged 108, the extremes being 96 and 124. About eighteen months before operation she had begun medical treatment, which consisted of electricity and injections, these covering a period of about five months. About two months after, having no relief, she changed advisers and was given thyroid tablets, which she took for a period of about three months without relief; indeed, being more nervous at times than before. When first referred to me she complained that at times she was very nervous, without any apparent or only slight cause.

Operation.—On April 18, 1903, entire right lobe, isthmus and about half of left lobe were removed under ether anesthesia.

Pathology.—Colloid hypertrophy of the thyroid. Patient made uneventful recovery. In September of same year patient's nervous condition was much better, and pulse at five different times averaged 92, the extremes being 86 and 104.

CASE 2.—Miss T. B., aged 32, was born and lived in Illinois all her life. Dressmaker for eight years.

History.—Patient had marked swelling of right lobe of thyroid for four years, with extreme nervousness and tremor, and had been treated for chronic indigestion because of many attacks of vomiting and diarrhea. At first visit, about six weeks before operation, pulse varied during one hour from 108 to 136. During the four days previous to operation pulse had extremes of 104 to 138. There was no exophthalmos.

Operation.—On May 3, 1903, under ether anesthesia, nearly the whole of the right lobe was removed. Three months subsequent to operation the tremor had disappeared, the patient was much less nervous and the diarrhea and nausea had disappeared.

Pathology.—Cyst of thyroid gland. Cyst fluid slightly discolored and thin. Specimen was lost in transit to laboratory, so no microscopic examination was made. Patient was seen Dec. 15, 1905; pulse, 88; weight increased seventeen pounds, and says she feels perfectly well.

CASE 3.—Mrs. H. W. T., aged 44, was born in Illinois and had lived in Iowa thirty-eight years.

History.—History of tremor, nervousness, nausea, vomiting, diarrhea, for four years. During the past six months the eyes were noticed to be moderately prominent. The pulse was said to run at times as high as 148. When first seen it was 126 to 134. The thyroid gland was only moderately enlarged; slightly more prominent on the left side.

Operation.—On Feb. 16, 1904, under cocaine anesthesia, the left lobe and isthmus were removed. Except for the day following the removal, when patient's pulse went to 126, the temperature to 102.8 and there was extreme restlessness, the recovery was uninterupted.

Pathology.—Sections showed typical invaginations of exophthalmic goiter.

On June 16, 1905, the following was received: "Your patient is fine. Her eyes have lost their prominence so much that it is hardly noticeable. She weighs 141 pounds" (weight at time of operation, 118). Her other symptoms have been so relieved that she had not called on the doctor for attention for over three months.

CONCLUSIONS.

1. Every irregular tumor of the thyroid, no matter how small, should be removed, as only by following this line of procedure can we hope to save the lives of those having malignant growths.
2. Every regular tumor of the thyroid causing symptoms other than deformity should be resected when, after a few months' medical treatment, its growth is not checked, and no improvement is shown.
3. Avoidance of trauma, care of the stump, free drainage and salt solution to keep full blood and lymph vessels, to prevent as far as possible wound absorption.

MUCOCELE OF THE APPENDIX.

WITH REPORT OF A CASE POSSIBLY CARCINOMATOUS IN NATURE.*

ALFRED STENGEL, M.D.

Professor of Clinical Medicine in the University of Pennsylvania.
PHILADELPHIA.

The somewhat indefinite term mucocoele may be retained because it sufficiently suggests the general characters of a condition, the exact nature of which is probably not always the same. In some cases the pathology seems clear; in others there is much uncertainty as to the process of formation; but in all there is a cyst-like appendix with mucoid contents. Such cysts, and in fact all kinds of cysts, of the appendix are comparatively rare. According to Kelly and Hurdon, Ribbert found six cases among 400 autopsies; Bryant, one case among 124 autopsies; Steiner, three among 2,286; Bordy, one among 528, and they themselves found sixteen cases recorded among 3,770 autopsies at the Boston City Hospital. I have seen but one well-defined case, that herewith reported, among about 2,000 autopsies.

The appearance of the diseased appendix is that of a rounded or pyriform cyst with a more or less definite constriction of the proximal portion of the organ. Sometimes the distal part or tip alone is dilated; in other cases the whole appendix is enlarged. The lumen may be completely occluded at the cecal end or merely narrowed. In some of the cases the obstruction was due to a kink produced by a bend or by a fibrous band. In one, at least (Treves and Swallow), the cyst contents flowed out when the appendix was straightened.

The contents of the cysts are either of a muco-purulent, sero-mucous, serous or purely mucoid character. Occasionally they are blood-tinged. A review of the reported cases will show that in all probability the cysts are of different pathologic character. Some are undoubtedly merely inflammatory retention cysts, caused by occlusion of the mouth or proximal part of the appendix. A number of such have come under my observation, all being of moderate size and quite evidently of inflammatory origin. Exceptional cases, however, may be of such size and may have lost the characters of inflammatory retention cysts to such an extent that they may be classified as cysts and may admit of much doubt as to the mode of formation.

LITERATURE.

Leube,¹ in referring to these inflammatory retention cysts, states that the contents at first consist of tenacious mucous, and that later the sac contains only a watery serum, because when the appendix becomes much distended its wall becomes thinned and its vessels more superficial. Thus the watery portion of the blood may escape more easily, and the formation of mucus is reduced to a minimum (*hydrops processus vermiformis*).

Sonnenberg,² in referring to hydrops of the appendix and to retentive cysts, after detailing the results of obstruction of the appendix, states that the retained secretion does not always cause a severe disease of the appendix. If the obstruction occurs at a time when the lumen of the appendix is free, or when virulent micro-organisms are not present, there is no decomposition of the secretions. A continued accumulation of secretion takes place and overdistension of the appendix in the form of a retention cyst may occur. The mucous membrane becomes compressed, epithelial cells are thrown off and the connective tissue elements hypertrophy. The muscular and serous coats of the appendix also thicken. Hernious protrusions of the mucous membrane through the muscular layer are occasionally met with, as in the case described by Kelynack and Ribbert. Such protrusions are also found in cases reported by Shoemaker and Kelly and in my own.

Among others the following reports refer to cases supposed to have had this character of retention cysts:

Wenzel-Gruber³ describes a case in which the appendix was 10 cm. long, the spherical sac at the top being 4.2 cm. long, the constricted neck 1.8 cm. and the pedicle or proximal portion 4 cm. in length. The diameter of the sac was 5 cm., of the neck 2 cm. and of the pedicle 1 cm. The wall of the sac was from 2 to 3 mm. thick, as were the walls of the proximal portion. The serosa was thickened, the muscularis hypertrophied and the mucosa convoluted. The cyst was filled with viscid glassy mucus. The patient had tuberculosis of the lungs and intestines. The author notes that the opening of the appendix into the cecum, 1 mm. in diameter, was very small, but must have been thus narrowed by the chronic inflammation.

Feré⁴ presented a mucocoele of the appendix, found at autopsy on a man 55 years of age, dead of disease of the kidneys. The appendix was sigmoid and fusiform, with a circumference of 9 cm. at the central dilated portion. The length was 10.5 cm. The appendix was quite free from adhesions and normal in color. On opening the cecum there was seen a fluctuating tumor the size of a walnut, covered with reddish mucous membrane, which was almost ecchymotic in spots. The contents of this tumor were continuous with the contents of the appendix. On section of the unthickened walls of the appendix a colorless gelatinous mass, resembling boiled starch, was turned out. This was found to be composed of mucus and a few cells. The mucocoele was probably consequent on an obliteration of the appendiceal opening, due to ulceration of the mucous membrane at this point. The tumor distended the wall formed by the mucous membrane of the cecum and the appendix, and thus produced the intracecal tumor. The condition had caused no symptoms.

4. Progres Med. Paris, 1877, vol. v, p. 73.

Other cases of cysts or of dropsies of the appendix are referred to by Bossard, Kraussold and Ribbert; and Wölfler describes a cyst found in an operation for herniotomy and which, on consideration of its characters, seemed to be a cyst of the appendix.

Bristowe⁵ calls attention to dilatation of the appendix which may occur when its orifice is obliterated or obstructed. "Then the appendix becomes elongated and plump (perhaps as thick as the little finger), presents often false diverticula (resembling, on a small scale, those of a sacculated bladder), and is distended with a glairy transparent fluid, the secretion of the mucous membrane."

Treves⁶ states that it is common to find the fore end of the appendix greatly enlarged and distended from the retention of mucus and other matters in the distal end of the canal.

Kelynaek says that this has not been his experience. He refers to one case under his own observation and to Fenwick's case,⁷ in which "the appendix was distended by a milky fluid, the communication with the cecum being obliterated."

Maylard⁸ describes a retention cyst of the vermiform appendix from a patient who had died of chronic Bright's disease. The appendix was free, four inches in length, normal for its proximal two inches, "but the distal portion was dilated into an egg-shaped, tense, cyst-like structure." The dilated part was shut off from proximal portion which communicated freely with the cecum. A mass of clear gelatinous substance was turned out of the cyst, leaving behind some "white, creamy-like material, in which was embedded a small calcareous concretion." The peritoneal surface was freely injected with blood vessels. Maylard notes that Coats⁹ has described a similar specimen.

Shoemaker¹⁰ describes a cystic condition of the appendix, discovered postmortem, not having given rise to symptoms during life. The cyst of the appendix was 4 inches long and 1¼ inches in its broadest diameter. "A small portion of the distal end was not dilated, and at about the broadest portion of the cyst was a thinned area seemingly about to rupture." The cyst contained a "clear jelly-like mass."

Biggs¹¹ reports two cases of stricture of the appendix. One appendix was 9 cm. long and 2 cm. in diameter, and the lumen was occluded .5 cm. from the origin by firm fibrous bands. "The contents of the appendix measured 2 drams, were of a slightly pinkish color, and consisted of fat globules, granular matter, and cholesterol crystals." The second appendix was obstructed by a kink near the tip, produced by traction of the peritoneum.

Hawkins¹² reports 2 cases of a condition which he calls "cystic appendix," which were cases of empyema of the appendix. He thinks these cysts may be caused by obstruction of the lumen due to kinking of the tube by an acute bend. He refers to a case reported by Treves and Swallow¹³ in which the cyst was 2 inches in length, very hard, and filled with mucus, which escaped when the appendix was made straight after its removal. The bent position had been maintained by old adhesions.

It is somewhat remarkable that in almost all the cases the condition was discovered accidentally at operations or autopsy or at least had occasioned no pronounced symptoms. If the accumulating liquid is of inflammatory nature, one might expect, in a greater number of the cases, active clinical symptoms, especially as the cysts often reach considerable size and not rarely have been attached by adhesions to surrounding structures. There is little doubt, however, that most of these cases were probably of inflammatory origin.

In some cases, a tumor was recognized in the right iliac fossa or the growth was of such size as to have made it probably palpable during life.

Coats¹⁴ mentions a case in which the appendix had been converted into a large cyst, measuring 5 inches in its long diameter. The cyst contained a tenacious material and the wall was thick and firm.

Wilks¹⁵ saw a case in which the appendix was dilated to the size of the ileum and distended with 3 or 4 ounces of white odorless mucus.

Wien¹⁶ reports a case of cystic degeneration of the appendix vermiformis, which caused a tumor in the right iliac fossa. There was great swelling along the crest of the ilium, and an opening near the posterior spine of the ilium, from which 3 or 4 ounces of quite clear mucus, occasionally stained with pus, were discharged daily. The discharge was said to look almost exactly like vitreous humor.

Guttman¹⁷ reports a specimen of enormous hydrops of the appendix, found on section of a woman 70 years old. The vermiform appendix was 14 cm. long and 21 cm. in circumference, and the opening into the cecum was completely constricted by strong fibrous bands produced by chronic inflammation of this part of the appendix. The secretion of the mucous membrane had become quite watery.

Montgomery¹⁸ describes a cyst of the appendix found in a woman during the operation of panhysterectomy. The cyst was 5½ inches long and 4¾ inches in its largest circumference. The contents were "apparently thin and watery." The cyst was removed.

Deaver's¹⁹ case presented a cystic dilatation of the appendix, the size of a small orange, which was adherent both to the neighboring coils of small intestine and to the right broad ligament. The lumen of the appendix was entirely occluded ¼ of an inch from its cecal end. The contents of the cyst were quite clear and somewhat tenacious. The author says that the mucous membrane is usually smooth and generally greatly atrophied as a consequence of mechanical pressure. There is also marked atrophy of the lymphoid follicles. If the distension be but moderate, it is not uncommon to find the wall much thickened as a result of compensatory hypertrophy of the muscular coats and also of some connective-tissue hyperplasia.

Occasionally, as in a case reported by Fowler,²⁰ there are active symptoms which necessitate operation. In Fowler's case the dilated portion, about the size of a small walnut, was at the distal end. There were no adhesions.

Though accurate studies of the pathology of the appendix have until recently been wanting, and especially in the class of cases above referred to, it is very probable

that most of the cases cited were retention cysts with inflammatory contents. Every one who has studied series of appendices must have encountered minor grades of cystic distension with contents of muco-purulent character. More advanced stages may cause empyema, and hydrops may occur in the appendix, as in the gall bladder.

There is, however, some reason to believe that there exists a quite different sort of dilatation of the appendix with which the inflammatory form may readily be confused. Long ago (1867) Rokitsansky reported four cases which he regarded as instances of colloid cancer and in which the gross appearance was that of cysts of the appendix. Virchow described these cases as colloid degeneration and figures one in his "*Krankhafte Geschwülste*."

In Rokitsansky's series of cases²¹ the appendix was transformed into a thick-walled cyst, varying in size from 2 to 6 cm. in length and from 1 to 2 cm. in diameter. The wall was made up of fibrous tissue, which replaced the coats of the appendix. The inner portion of this capsule was a loose areolar layer, with brownish pigment here and there, and in places it was lamellated. His observations pointed to the fact that this layer might be the remains of an atrophied reticulum. The contents of these appendices consisted of a whitish-yellow gelatinous substance, supported in two cases by a fine reticular network, with small rudimentary blood vessels visible in places. After considerable discussion of the subject, Rokitsansky comes to the conclusion that this affection is a colloid-cancerous degeneration of the appendix, and that the tension of the mass of gelatinous canceromatous material causes a dilatation of the walls of the vermiform process, with a consequent transformation into a fibrous capsule.

At the time of Rokitsansky's report little was known regarding the occurrence of carcinoma of the appendix, only two cases, those of Merling (1838) and of Prus (1865), having been reported. Recently, however, a considerable number of cases have been recorded, and Kelly and Hurdon tabulate a total of 52, including 2 which were designated endothelioma. They refer to Rokitsansky's cases, though erroneously stating that these were not examined histologically.

In 1884, Draper²² reported a case of colloid cancer of the appendix vermiformis. "The upper third or head of the appendix was enlarged and dilated to such a degree that externally it was of the size and shape of a large plum; its cavity, deeply injected, was irregular in its surface, and would admit the little finger. The opening to the intestine from the appendix was also dilated. The thickened wall of this enlargement presented the characteristic appearances of colloid disease." The tumor had caused symptoms and was probably the cause of death.

The features of this case differed somewhat from those usually described. The thickening of the walls of the diseased appendix and the dilatation of the cecal opening contrast strongly with the usual conditions.

Vimont²³ reports a case of mucocele of the appendix, found at the autopsy of a woman who had been operated on for bilateral gelatinous cysts of the ovary, which had ruptured into the peritoneal cavity. The tip of the appendix was found attached to the uterine cornus. The shape of the appendix resembled that of the stomach, with the small end attached to the cecum by a

small pedicle. The appendix was 11 cm. long and 12.5 cm. in circumference at the larger extremity. The contents were gelatinous, like boiled starch, and weighed 38 grams. The walls of the appendix were thickened, whitish, and at one place presented two small papillomatous masses. The author asks if this dilatation may not have been due to compression caused by the ovarian cysts.

This case even more definitely establishes the neoplastic nature of certain mucoceles.

Baillet²⁴ exhibited a cyst of the appendix found during an operation performed to remove a papillomatous-ovarian cyst. The orifice of communication with the cecum was occluded. The cyst was found to be made up of mucoid tissue, embedded in which were many large cavities lined with non-ciliated cylindrical epithelium.

PERSONAL CASE.

The case which came under my own observation occurred in a woman aged 50, who had had glycosuria for a number of years and finally died of rapidly developed acidosis. I had not seen her during life, but made the postmortem examination, at which the enlarged appendix was discovered.

Autopsy.—Performed March 18, 1899.

The body was that of a very large white woman, probably 5 ft. 10 in. in height, and quite fat. Rigor mortis was well developed. On section into the body, the subcutaneous fat was found excessive, being in places as much as an inch and one-half in thickness. The fat itself was of a light yellow color, and the muscles were rather lighter colored than normal. The pleural cavities were free of exudation, and there were no adhesions. The anterior mediastinum was occupied with a considerable excess of fat, so that the heart and pericardium were completely covered. On section into the pericardial sac, a little clear fluid was discovered. The epicardium contained an excessive deposit of fat at the auriculo-ventricular furrow on the right side and over the root of the great vessels, but not much anywhere else. The coronary vessels were distinctly seen as white streaks, the whiteness being due to the fibrous character of the walls of the vessels. The root and larger branches were so sclerotic that when cut transversely and compressed they immediately sprang open from the stiffness of their walls. The heart muscle was flabby on both sides, and there were some fatty patches here and there. The endocardium was white in places, and there were marked patches of atheroma in the anterior mitral leaflet, as well as in the root of the aorta around the mouths of the coronary vessels and at the edges and floor of the sinuses of Valsalva. The valvular orifices were normal, as were also the leaflets of the aortic and pulmonary valves. The tricuspid leaflets showed slight thickness at the edges.

The lungs were congested at the bases and somewhat edematous, but there was no marked change.

The abdomen contained an immense quantity of fat in the mesentery and omentum. The gastro-intestinal tract presented no abnormalities, except in the region of the appendix. The latter was found greatly distended in a somewhat cystic fashion, and at one point a small hernious protrusion of the mucosa, through a defect in the serous and muscular coats, causing a clear vesicular projection of about the size of a grape seed, was discovered. The mouth of the appendix seemed to be occluded, but the bowel was kept unopened for subsequent dissection. The coils of intestines were everywhere more or less matted together by thin, veil-like adhesions, but there were no gross adhesions of any sort.

The liver was much enlarged and compressed by the ribs (*Schnurr Leber*). On section, its substance was rather flabby, and spots and streaks of light color were discovered. There was evidently some slight sclerosis and also a considerable degree of fatty change.

24. *Bull. de la Société Anat. de Paris*, 1891; 55, vol. v, lxxi, p. 67.

The pancreas was soft and presented no macroscopic change. The spleen was enlarged, fully twice its normal size, and the capsule was rather hard. The substance was soft and rather light in color, with spots of dark, almost hemorrhagic, appearance. The splenic artery was atheromatous in a high degree, and the splenic vein greatly increased in size. The kidneys were a little enlarged. The cortex was rather wider than normal, and the substance deeply congested. There was no definite visible disease. The suprarenal capsules were normal.

The abdominal aorta and its branches, as far as they could be felt, were sclerotic, though much less so than the splenic artery.

The uterus and its appendages were normal.

Description of Cyst.—The appendiceal cyst was found to be about 2½ inches in length and a little over 1 inch in diameter at its thickest part, which was near the middle of the organ. The cyst extended from the cecum to the tip of the appendix. At the cecal attachment the lumen was occluded and the expansion to the cyst was sudden, as if a much enlarged appendix had been constricted at its origin by a tightly drawn encircling ligature. The unopened cyst was quite firm and elastic, giving the impression of a sac tensely distended with gelatinous matter (Fig. 1). The wall was white and glistening on the outside, and the small blood vessels showed plainly in the serous covering. On transverse section, the cyst was found to be of semi-solid consistence; its walls tough and fibrous, 1 to 2 mm. thick, and in most places cleanly separated from the whitish or opalescent gelatinous contents (Fig. 2). The latter were easily shelled out when the thickness and firmness of the walls prevented their collapse, leaving a firm shell.

Microscopic Examination.—Microscopic examination showed the wall or capsule of the cyst to consist of a thickened and fibrous muscularis and serosa (Fig. 3). The submucosa was of loose areolar character, containing considerable leucocytic infiltration and new-formed spindle cells. The mucosa was nowhere intact. In its place was found a layer of varying thickness, composed of polymorphous epithelial cells without definite arrangement. Generally this epithelial lining was thin and in some places wanting; in a few places it was more massive, and at such places there could be traced into the gelatinous cyst contents, irregular extension of columns or strata of epithelial cells.

Cyst Contents.—The contents of the cyst were made up of a lamellated gelatinous substance of compact character. Between the lamellae were found cells (leucocytes) and many minute spherical bodies staining deeply with hematoxylin (calcareous spheres, Fig. 4), and here and there masses of irregular epithelial cells or less frequently ill-defined glandular acini. While the epithelial cells were more numerous near the periphery, that is, just within the capsule, they could be found at the very center and scattered everywhere through the gelatinous substance. There was no evidence of a well-developed reticulum, but in places the irregular course of the gelatinous lamellae and the presence of short strands of spindle cells lying end to end suggested an old reticular arrangement. Nearly all the cells within the gelatinous material were degenerate, the groups of epithelial cells in particular.

The appearances strongly indicated some active cellular process with mucoid degeneration rather than an exudation from a diseased, but more or less intact, mucous membrane. The presence of acini deeply embedded in the gelatinous material and of irregular heaps of polymorphous epithelial cells further confirmed the suspicion that the process was akin to that of gelatinous carcinoma elsewhere.

There was no evidence in any of the sections of invasion of the walls of the appendix by a heterotopic epithelial process, though here and there in the submucosa small collections of epithelioid-like cells could be identified. It is possible that a more extensive sectioning of the appendix might have discovered definite invasion, but at the time when the sections were made no suspicion was entertained of a possible malignant nature of the condition.

It may be recalled that in some of the reported cases, such as that of C. C. Norris,²⁶ but little invasion of the walls was

evident, the growth appearing, in the main, as a mass within the lumen of the appendix.²⁶

Chemical Examination.—Chemical examination of the contents of the cyst showed the presence of considerable quantities of calcium which the microscopic examination had indicated. The fact that the mucoid material was a mucoprotein of the same general character as those met in gelatinous tumors of the ovary and the like seems to me of some importance, though not a certain proof of the nature of the condition.

Dr. Edsall reported his chemical study of the cyst contents as follows:

"The substance from the interior of the appendix was (after preservation in alcohol) of somewhat the same consistency as a dense jelly. It was of grayish-white color, partially opaque. It was soluble in water, forming a slightly glistening solution. On boiling, the solution became opalescent, but did not coagulate. It did not coagulate on the addition of acetic acid. Absolute alcohol produced a precipitate which was still readily soluble in water after standing under alcohol for more than 24 hours. After boiling with 2 per cent. sulphuric acid, the substance reduced Fehling's solution readily. The lack of coagulation after adding acetic acid is sufficient to indicate that it was not mucin; the solubility in water distinguished it from colloid. The reactions are those characteristic of pseudomucin. After allowing the preserving alcohol to evaporate from two small portions of the substance, these portions were weighed, incinerated, and the calcium of the ash determined. In the two instances the weight of the calcium (as Ca O) was, respectively, 1.1 per cent. and 0.85 per cent. of the total."

It must be admitted that the nature of the process in the appendix I have described is somewhat uncertain. At first I was disposed to think it simply a dilated appendix filled with mucoid material unusual in amount and character. Closer study, however, and in particular the discovery of irregular acini, epithelial tubular structures and collections of epithelial cells scattered everywhere through the gelatinous substance made me suspicious that the condition might be allied to colloid carcinoma. A review of the scant literature of the subject and especially the features of the cases reported by Vimont and Baillet seem to lend some support to my suspicion.

DISCUSSION.

DR. WALTER L. BIERRING, Iowa City, Iowa, said that he had seen only one case that bore any resemblance to the interesting condition described by Dr. Stengel and this was evidently not identical. An enlarged appendix, obtained at operation, measured 3½x1½ inches, and resembled a retention cyst, the entire mass having an elliptical form. The content was composed entirely of gelatinous mucoid material; at first it was thought to be purely an evidence of a perverted secretion of the lining epithelium due to chronic inflammation, following which the excessive mucoid substance had become retained in the dilated appendix, but the fact that portions of the mucosa and the other coats of the appendix were replaced and invaded by this same material made it appear, in part at least, like a retrogressive tissue change. Dr. Bierring said that the question

²⁶ Since the above was written, an interesting specimen has been shown me by Dr. A. J. Smith, to which I am permitted to refer by his and Dr. B. C. Hirst's courtesy. Dr. Smith writes as follows:

"Appendix was removed in Howard Hospital in June, 1905, by Dr. B. C. Hirst, from a negro woman; character of case was not appreciated prior to operation. The woman was supposed to have bilateral pelvic growths. At operation both ovaries were found much enlarged and the seat of widely infiltrating papillary adenocarcinoma, with surface papillary extensions, with both tubes and peritoneal surface of uterus similarly involved. Appendix was free, short, with smooth and pale and glistening exterior, but with distal extremity distended into a small rounded cyst-like dilatation. On section the latter was found filled with clear mucus, the walls grossly showing no thickening save at one or two points where there were tiny white subserous nodules, which may possibly be foci of starting invasion from the cancerous growth of the genitals."

The appearance of the gross specimen was strikingly similar to that of my own.

Fig. 1.—Slightly reduced view of the cecum (a) and appendix (b). The mesentery of the appendix was heavily loaded with fat (c).

Fig. 4. Calcareous spheres imbedded in the gelatinous substance within the appendix. Zell's, oc. 1; obj. 1 12. Specimen stained with hematoxylin.

Fig. 3.—Section of the wall of the appendix and part of the substance within. Toward the center of the appendix is seen (a) an acinous or section of a glandular tubule; at (b) an irregular mass of epithelial cells suggesting by its position and the relations of adjacent structures that it had been separated from the mucosa. No remains of normal mucous membrane are observable.

Fig. 2. Transverse section of the appendix showing the stiff walls and opalescent mucoid contents. Life size.

The Value of Brief, Pointed Practical Articles.—Dr. George J. Monroe said in the *Cincinnati Lancet-Clinic* about a paper which he wrote: I am not gifted with a large vocabulary of words, yet on reading the first paper I prepared I found that it took me fifty-four minutes to read it. I had not then said all I wanted to. I began to eliminate and condense. I rewrote the paper. I found that it took thirty-two minutes to read this paper. Again I rewrote the paper, and on reading it this time I found that it only required nineteen minutes. I compared this paper with the first and second, and I was surprised to find that I had really said more than I had in either of them. This will apply to the majority of papers read before medical associations. The greater number of them

could be materially condensed and yet contain all that is expressed in the long papers. How many papers we find that are filled with useless matter that has no relation to the subject. What cares the busy doctor about a lot of statistics and data (that have been published elsewhere and that can be looked up by anyone interested)? We want to learn the best way to diagnose and treat these diseased conditions.

PLEXIFORM NEUROFIBROMA.*

FRANK B. WYNN, M.D.
INDIANAPOLIS.

The plexiform type of neurofibroma is considered by Recklinghausen, Kyrieleis, Kricge, Hurthle, Teichert, Westphalen and others to arise invariably from the connective tissue of nerve trunks. In opposition to this view, Lahmann maintains that such neoplasms may not only originate in the connective tissue of the nerve trunks, but also from that of the blood vessels or of the skin glands or hair follicles as well. His findings have been corroborated in whole or in part by Philippon, Du Mesnil, Verneuil and Löwenstein. Bearing on this mooted question, the following case may present some features of interest:

Family and Personal History.—R. E., the unfortunate subject of this report (Fig. 1), is aged 19 years. His parents,

Fig. 1.—Photograph of the patient.

five brothers and two sisters are living and healthy. There is no hereditary taint. His training in an institute for the blind was thorough, and, all things considered, he is exceptionally bright and well formed. He has never suffered from any malady except the one described.

History of Case.—Undue prominence of the cycloids was noted at birth. Almost at once there developed a catarrhal conjunctivitis, accompanied by extreme photophobia. Later keratitis arose, followed by ulceration of the cornea with subsequent fibrosis. From all that can be learned blindness must have supervened at a very early age.

Swelling of the eyelids, especially the upper, was an early manifestation, as indicated in a photograph taken at 2 years of age. At 8 the eyes were closed. Three years later (1897) the bulging and bagging of the upper lids became so great that surgical measures were instituted. A large section of the redundant skin was removed with a lemon-sized mass of neoplastic tissue from either orbit. Gradual recurrence of the growth followed the operation.

* Read in the Section on Pathology and Physiology of the American Medical Association, at the Fifty-sixth Annual Session, 1905, 1906.

Fig. 2.—Plexiform Neurofibroma. Showing arrangement of five cords around the large vessel ($\times 12$).

Fig. 4. Large vessel in which is shown a nodular arteriosclerosis.

Fig. 3. Showing arrangement of four cords about a large vessel ($\times 8$).

About the fourth year of age tenderness was first noted over the right temporo-parietal region and at a point midway between the mastoid prominence and the occipital protuberance. In these respective regions there slowly developed a dense, diffuse enlargement, to which the skin soon became attached. Within the past eight years growths precisely similar in size and location have appeared on the left side of the head.

Fig. 5.—Same as Fig. 4, under high power showing degenerative change in intima and media.

A few years following the appearance of the growths in the orbits and on the skull, irregular, easily-movable masses developed in the subcutaneous tissue of the right and then of the left cheek. Extension took place over the angle of the right jaw into the parotid region. More or less tenderness has characterized the growths wherever found.

Status Præsens.—Weight 98 pounds, height 5 feet 1 inch. The bones are small; trunk and extremities delicately shaped. Sensorium clear. Deficiency of musculature and adipose tissue. Examination of the nervous system and of the thoracic and abdominal viscera gives negative findings. There is some pallor of the skin. A blood examination gives hemoglobin, 78 per

Fig. 6. Showing fibrous structure of growth and small vessel in which there is extensive subendothelial proliferation.

cent.; red cells, 4,470,000; leucocytes, 10,400. The striking thing on inspection is the gigantic head on a dwarfed body. The measurements of the head are: Circumference, 26 inches; anteroposterior diameter, $9\frac{1}{2}$ inches; transverse diameter through temporal region, $8\frac{1}{2}$ inches.

Over each temporo-parietal region and extending slightly on to the forehead are palm-sized enlargements intimately con-

Fig. 7.—High power enlargement of vessel shown in Fig. 6. Subendothelial proliferation.

nected with or a part of the bones. Just posterior and superior to the mastoid prominence on the right side is an egg-sized enlargement of similar nature. All these growths on the skull are characterized by tenderness, bonelike hardness and firm attachment of the overlying skin. The skin over these localities, and in fact wherever adherent to the underlying growth,

easily palpable, fill the orbital cavities. Similar flattened masses of hard convoluted cords are felt, freely movable in the pendulous folds hanging from either cheek.

Histologic Study.—The patient consented to an exploratory incision for the purpose of removing one of these masses for microscopic study and diagnosis. Through a two-inch incision

Fig. 8. Showing two vessels with extensive subendothelial proliferation; red cells seen in one lumen; smooth muscle cells.

Fig. 10. Low power showing transverse section of small cord in which is an area of smooth muscle fibers.

shows brownish, mottled pigmentation. Having the same distribution as the pigmentation are peanut to hazelnut-sized areas of epidermal thickening, resembling sebaceous warts.

The skin of the face hangs in great lobulated folds over the lower jaw and from the orbits on either side (dermatolysis). The lips are enormously thickened. The lower eyelids are

tortuous white cords from two to six millimeters in diameter were plainly visible. The resemblance to sclerotic vessels was very striking. The strands were of uniform thickness (not beaded) and loosely imbedded in the subcutaneous areolar tissue. An interesting fact is their arrangement in groups of from two to five strands, parallel and surrounding a large ar-

Fig. 9. High power showing fibrillae in central portion of cords.

rected and coarsely granular. No ocular structure is visible on the right, but on the left at the inner canthus the remnant of an eyeball is seen, which shows a densely sclerotic cornea and is capable of slight movement. Both eyeballs may be palpated as very hard and reduced in size. Firm fibrous adhesions bind the palpebral conjunctiva to underlying structures, except for the border of the lids. Irregular, hard, wormlike masses,

Fig. 11. High power of Fig. 10 showing the nonstriated muscle cells.

tery. (Fig. 2.) On cross section these cords presented a light, translucent, almost transparent appearance.

Microscopic study reveals several features of interest.

1. The predominant histologic structure of these cords (Figs. 9 and 10) is a dense fibrous periphery with a central meshwork of fine fibrillae, in which there is a sparse distribution of

nuclei, round and spindle-shaped. The arrangement suggests a resemblance to perineural connective tissue surrounding a nerve bundle in which there has been proliferation of the endoneurium with degeneration of the nerve fibers. Staining with polychrome methyl-blue fails to give the reaction for mastzellen. Unna considers the presence of the latter cells as highly characteristic of neurofibroma.

2. After staining by the Weigert method, careful search has failed to reveal any nerve fibers.

3. Vascular changes: The large arteries (Fig. 4) show nodular arteriosclerosis with thickening of the intima and some degenerative change in the media. More interesting are the changes in some of the medium-sized smaller vessels. By extensive subendothelial proliferation a wide zone of large cells is formed, surrounded by a rim of fibrous connective tissue, mixed in some instances with smooth muscle fibers. (Figs. 6 and 7.)

Examined in cross-section under a low power, the first impression produced is of a nerve bundle surrounded by its perineurium. But close study reveals a central hunch with endothelial lining in all the various areas of this character, showing the vascular nature. If the contention of Lahmann and others that the so-called neurofibroma may sometimes arise from the connective tissues of blood vessels is correct, may it not be possible that the lesions as described above represent an early period in the evolution of the growth?

4. Another histologic factor of interest revealed in the study of the specimen is the presence of non-striped muscular tissue within the fibrous cords.

DIAGNOSIS.

In its clinical aspects the case described seems to be one of plexiform neurofibroma; that is, a new growth arising from the connective tissue of a nerve trunk. Studied pathologically, this is not proved, although it is possible that such complete degeneration of the nerve fibers may have occurred that histologic origin may be difficult to trace. On the other hand, the contention of Lahmann and others that these growths may arise from vascular structures is supported by the following findings in the case:

- (a) An absence of nerve fibers and of mast cells.
- (b) The arrangement of the strands parallel to and surrounding the arteries.
- (c) Extensive proliferation about the smaller vessels.
- (d) The presence of smooth muscle tissue in the tortuous cords which constitute the chief gross pathologic feature of the neoplasm.

ETIOLOGY AND PREVENTIVE TREATMENT OF SCARLATINAL NEPHRITIS.*

II. LOWENBURG, A.M., M.D.

Lecturer on Pediatrics in the Medico-Chirurgical College; Pediatricist to St. Joseph's Hospital Dispensary; Assistant Pediatricist to the Medico-Chirurgical Hospital and the Philadelphia General Hospital.

PHILADELPHIA.

In presenting a paper on the etiology and prevention of scarlatinal nephritis, it is not my purpose to attempt any addition to our knowledge, but rather to emphasize the importance of already-known facts. In striving to control any morbid process, that system of therapeutics should be regarded as best which attempts the destruction of etiologic factors or seeks to mitigate their malign influences on the economy. In dealing with the acute infectious diseases the greatest advances have been made along the line of prevention.

This fact has received special emphasis in those diseases in which the habits of the several specific germs and their means of transmission have been carefully

studied. This has been notably illustrated in tuberculosis, diphtheria, malaria and, more recently, in yellow fever. Many diseases are rightly regarded as specific even in the absence of evidence sufficient to demonstrate any special organism as the active agent. Among diseases of this character scarlet fever stands pre-eminent. These diseases are best prevented by applying to them the same principles of isolation, disinfection and quarantine which are of value in preventing those maladies which are known to be specific. After the inception of such a disease, in the present state of our knowledge, our province is not to attempt to abort or to cure, but to recognize the possible complications and sequelæ in order that we may either prevent them or mitigate their severity. With respect to scarlatina this is especially true. The disease is self-limited and entirely uninfluenced by drugs. The formerly much-valued specifics, sodium benzoate, sodium salicylate, belladonna, etc., have been justly discarded as such. The greatest mortality and morbidity of scarlet fever must be accredited to its complications and sequelæ, which are more far-reaching and produce more human wrecks than those of any of the acute infectious exanthemata.

SCARLATINA AND NEPHRITIS.

Not the least interesting of these complications and sequelæ is nephritis. As humanitarians, as well as physicians, it becomes our function to note carefully the etiologic factors concerned in the production of this serious ailment in an attempt to apply such knowledge to its prevention.

The types of this affection are exceedingly variable. From a careful study of the urine it may be learned that, in the beginning, there occurs a form of albuminuria, sometimes associated with a few hyaline casts and epithelial scales, which is more or less common to the initial febrile stage of nearly all the acute infectious diseases. Then there is noted the acutely septic form of kidney disease which occurs as a complication in the very malignant cases which are rapidly fatal. So rapid is the course that suppression of urine and death from uremia occur here often without edema. This type of nephritis is perhaps best described as a part of a universal sepsis, the toxin of which spends its greatest force on the renal tissue. Occurring in varying degrees of severity we have also that well-known form of renal involvement which makes its appearance during the third and fourth week of the disease or after convalescence has been established. This is the so-called post-scarlatinal nephritis, and occurs with a more or less insidious onset, and unless detected early, may lead to serious chronic kidney disease. There is also met what may be designated recurrent intermittent post-scarlatinal albuminuria. This form has received little if any attention at the hands of medical writers, and yet its existence must have been noted by those who have had a greater clinical experience than I. This form of albuminuria occurs in many of those cases which have suffered from even a mild post-scarlatinal nephritis. It is influenced greatly by exercise and diet. Excesses in both these factors act as exponents of an attack, while a reduction in both is universally preventive and curative. The condition, in my limited experience at least, is compatible with apparently robust health. I have noted it at least two years after an attack of scarlet fever. I have not been able to detect tube casts associated with it.

ETIOLOGIC FACTORS.

Scarlatina is a disease peculiarly suited to the occurrence of nephritis. During an attack of this disease,

* Read before the Northern Medical Association, Oct. 27, 1905.

covering a period of from four to eight weeks, perhaps, there is, during the first half of this time, at least, almost complete destruction of skin function. In this manner the disease is not entirely unlike a severe burn of the first degree both in appearance and in its effect on kidney substance. The kidney, already overworked and overirritated, is thus forced to compensate for this loss of skin function.

Other important etiologic factors may be found in the increased toxicity and the increased acidity of the urine. Of the two the former is by far the more important. Whatever the real poison of scarlet fever may be, without doubt it is removed from the economy via the urine, and, unfortunately, it seems to possess a peculiarly irritant effect on the kidney. This statement receives color from the fact that from apparently the mildest attack of scarlet fever may follow the most serious and persistent attack of nephritis. In fact, J. Lewis Smith records a case in which a mother, previously known to be healthy, while nursing her son who was suffering from scarlet fever, complained of symptoms which led to a urinary examination which revealed albumin and casts. Smith regards this as a case in which the nephritis was the only symptom, and cites it as an example of the severely irritating effect of the scarlatinal poison on the kidney. The patient in this instance made a perfect recovery. The frequency and seriousness of kidney irritation has received emphasis from the work of Sørensen, who has demonstrated postmortem renal lesions in patients who exhibited no clinical features of the disease. This statement seems to prove that the irritant is local and produces the morbid changes early. In order to be local it must be in solution in the urine. J. Lewis Smith also cites the cases of four girls in the same family who suffered from desquamation nephritis, after only one of the four had had scarlet fever.

The increased acidity of the urine can be readily determined by analysis. While not such a potent factor, its influence as a producer of kidney irritation can be readily assumed. It is probably the cause of the early albuminuria and, unless permitted to continue, does not cause serious degenerative changes in the renal tissue. The recognition of this fact has an important bearing on our efforts to prevent this affection. The relationship between the concentration of the urine and its acidity is a positive one, and therefore it, too, becomes an important etiologic factor.

Constipation, by preventing the escape of morbid material via the intestinal tract, thereby permits an increase of the toxins in an already overloaded urine. In this manner it may assume the rôle of an important contributory agent. The same may be said of diet. Dietary indiscretion may be nominated as the most important of any one single causal factor. This is especially true when highly organized proteid substances, such as meats, are too early added. These substances act by increasing the toxicity and the acidity of the urine.

The influence of cold can not be entirely disregarded. Its place, however, as a cause of scarlatinal nephritis has not been fully defined. In discussing this point Tyson remarks that "children have been found barefoot in the street with the eruption on them, and yet have escaped Bright's disease." In detailing the prophylaxis of the latter, the same author, however, proceeds thus: "Whatever may be the immediate cause of the renal involvement, it is certain that cold often becomes its exciting cause." Jacobi affirms that "exposure and sudden changes of temperature will always hold their place in

etiology, in the minds of those who do not forget to notice the living case besides the microscopic excrement." My own belief is that it is a factor of much importance in susceptible and anemic cases. The greatest danger lies in a poorly-regulated room temperature, sudden draughts and sudden chilling of the surface by careless bathing. By these means the blood is rapidly driven from the surface capillaries and intense congestion of the internal viscera results.

PREVENTIVE TREATMENT.

The patient should be placed in a well-ventilated room, the temperature of which should be about 68 to 70 degrees, and should be kept uniformly even. If possible, a room of southern exposure is to be selected. Draughts and sudden changes of temperature are to be avoided.

Diet.—A careful regulation of the diet is essential to the prevention of nephritis. The best diet for scarlet-fever patients is milk. It may be given modified to suit the age if the patient be a healthy bottle-fed baby. If a nursing, maternal milk should constitute the sole source of nutriment. The milk is to be secured with a breast pump. Older children may be given whole milk or milk diluted with a cereal water, lime water or Vichy. If digestion be weak the milk is best exhibited peptonized. However given, milk should be practically the sole article of diet for a period covering from four to six weeks or until desquamation is complete. Experience bears out the observation of Jacoud that an absolute milk diet is of great service in preventing nephritis. Fruit juices serve a useful purpose by rendering the urine alkaline, and they are very refreshing. Toward the end of the period of desquamation freshly cooked tender vegetables, fruits and farinaceous substances may be cautiously added. Proteids may now be carefully given and only in small quantities. These are gradually increased in quantity and quality as tolerance is established. Throughout the course of scarlet fever, from the beginning, and, especially following each change in diet, the urine should be submitted to a careful daily analysis. On the appearance of the least trace of albumin a return to an absolute milk diet must be made at once.

Hydrotherapy.—Asked to designate any one single remedy which is of the greatest service in preventing scarlatinal nephritis, I should unhesitatingly name water. Its free and continuous use is indicated for the reason that, by increasing the amount of urine, it dilutes toxins and diminishes the acidity, thereby lessening kidney irritation. By stimulating catharsis and diaphoresis the elimination of toxins is facilitated. Water can be employed with advantage in three different ways: by mouth, balneotherapy and by enteroclysis, a combination of all these methods being productive of the best results. It is my practice to order a definite amount of water to be given with as much regularity as the food. It is best given between feedings. If plain water can not be readily taken use may be made of the various mineral waters as Poland or Celsin's Vichy, or, better yet, it may be exhibited as lemonade or orangeade. To a pint of either of the last two may be added, with advantage, a teaspoonful of cream of tartar.

A daily bath, given with friction, is a valuable adjunct. Aside from being the only means to be employed to reduce temperature, it increases the capillary circulation of the skin and thus relieves internal congestion. The bath must be given carefully, otherwise serious chilling of the surface will ensue and the purpose for which it was employed will be defeated. For this reason the full

tub bath is best, the child enveloped in a blanket being completely immersed. A dry blanket is warmed and held ready to receive the patient when the bath is completed. This is followed by free diaphoresis. If the full tub bath can not be used, it may be replaced by sponging, care being taken to sponge only one part of the body at a time, while the rest of the surface is kept covered. The temperature of the water is regulated by the temperature of the patient. It should never be more than five or ten degrees lower. For young children and infants the warm bath is always desirable. Its effect on temperature is often amazing and the diaphoretic effect is always beneficial.

Enterocolitis is a valuable prophylactic agent. From one to eight ounces of normal saline solution should be thrown into the rectum to be retained once or twice a day. It lessens thirst, reduces fever, prevents constipation, lessens toxemia and allays renal irritation.

Medicinal.—The only drugs which are of any value in preventing renal complications are alkalis and laxatives. Urinary antiseptics possess little if any controlling influence. The administration of urotropin is useless and expensive. The salts of the organic acids as the citrate or acetate of potassium are changed to alkaline carbonates in the blood and are eliminated as such in the urine. They thus overcome the acidity of the urine, thereby destroying an etiologic factor of some importance. They are given in the dose of five to ten grains. From the beginning of the attack and throughout the course of the disease minute doses of calomel should be given at intervals of every three or four days. These are best followed by broken doses of magnesium sulphate conveniently dispensed as follows:

R. Magnesii sulphatis.....	gr. v-x	3-6
Ac. acetici diluti.....	m. v	3
Syr. zingiberis.....	mx. x	12
Aqua dest. q. s. ad.....	℥i	30

M. Sig.: A teaspoonful every two or three hours in water.

Antitoxin.—As noted before, the specific organism of scarlet fever has not been determined. Of all the organisms found the streptococcus seems to be the one most often present. It is nearly always present in the discharge from an otitis media, and has been recovered from the renal tissue. For these reasons it is regarded by some authors as the primal cause of the complications. This view is accepted by Charlton, who, however, regards the presence of the streptococcus as the result of a secondary infection. For this reason he employs Moser's antistreptococcic serum early in the treatment of scarlet fever. Escherich and E. von Leyden comment favorably on the use of this serum for the control of the general symptoms, but assert that it does not influence the occurrence of complications. Moser himself believes that his serum has a beneficial influence on the grave forms of scarlatina, but that it does not prevent nephritis.

Pernicious Anemia.—Menetrier, Aubertin and Bloch report a case of essential pernicious anemia in which by feeding with red marrow and attention to general nutrition the number of red corpuscles increased from 680,000 to 3,000,000 in a short time. They conclude that in every case of grave cryptogenic anemia, when there is a myeloid reaction, however feeble, it is advisable to try medullary opotherapy. In certain rare cases where the myeloid reaction is marked this treatment by reinforcing and regulating the efforts of the organism itself may cause an increase of the blood globules and at least a temporary cure. Where there is total absence of myeloid reaction this treatment is absolutely without effect.

Special Article

THE PHARMACOPEIA AND THE PHYSICIAN.*

SALINE CATHARTICS.

CHAPTER VIII.

A salt may be defined as a substance resulting from the chemie union of an acid with a base. For the present purpose we shall exclude from this classification salts of alkaloïds and of other organic bases, and confine our definition to the popular conception of salts, or purgative salts.

The purgative salts, in contrast to the antiquity of many of the vegetable cathartics, are of but comparatively modern use, many of the inorganic salts being introduced into Europe by the Moors, but not coming into general use until after the time of Paracelsus.

Most of the purgative salts have a disagreeable, bitter taste, but when taken in an effervescent draught this bitterness is masked, and the effervescent salts have therefore come into great popularity. The widespread use of nostrums of this type, instead of the official effervescent salts prepared by the pharmacist, illustrates an unfortunate condition which exists without a sufficient reason. There is too much distrust of the pharmacist by certain physicians, who complain that pharmacists are unable to supply preparations equal to those of the nostrum-maker. This may possibly be true in isolated cases, but the proof to the contrary is furnished by the extreme simplicity of the preparation of the effervescent salts which the average pharmacist can prepare quite as well as the large manufacturer. Nevertheless the proprietaries of this class have an enormous sale.

It is unfortunately true that the physician often lacks confidence in himself and prefers to use the ready-made mixture rather than to exercise his own choice. This is degrading alike to medicine and to pharmacy.

It is a part of our present purpose to illustrate the ease with which the physician may choose his own agents in the proportion which seems best adapted to each individual case, with the assurance that any honest pharmacist can compound his prescription in a form equal in efficiency and elegance to the nostrums.

The preparation of the effervescent salts depends on the fact that tartaric and citric acids and sodium bicarbonate may be kept in contact without change when dry, but unite with effervescence when they are dissolved in water.

As an example of the ease with which effervescent salts are prepared, we give directions for making one, which, though extremely simple, is still the most complex of those which are official. The Effervescent Magnesium Sulphate. The same directions, with slight modifications, are used in preparing the other official granular effervescent salts and may be used when it is desired to include other salts or even caffeine and similar substances.

The magnesium sulphate is dried over a water bath, powdered and mixed with powdered citric and tartaric acids, then with the sodium bicarbonate; the mixture is heated to about 95 °C. in a dish placed in an oven until it becomes moist; it is then rubbed through an ordinary tinned iron sieve (which forms it into granules). These are then dried at a temperature of 54 °C.

Does it seem credible that any pharmacist is unable to make so simple a preparation as that?

Many of the nostrums that are offered to physicians as effervescent saline mixtures are not even granulated, and some of them, at least, depend entirely on the use of the cheaper tartaric acid and sodium bicarbonate to produce effervescence. Mixtures of this kind can be prepared extemporaneously quite

* We have received letters calling attention to an apparent discrepancy in the dosage of codein as given in Chapter II of this article, Dec. 23, 1905, p. 1553, and in Chapter III, Jan. 13, 1906, p. 318. In Chapter II, the dose is given as 1/20 of a grain, and in Chapter III it is given as 1/2 grain. In the first instance referred to it was the intention to give the dose of codein as 3 m. (1/20 grain), when the drug is used as a sedative in expectorant mixtures. The average dose, of course, is generally double that of morphin, or 30 m. (1/2 grain).

as readily as the frequently prescribed liquid preparations, and we shall give several typical prescriptions in connection with the descriptions of the various salts.

Constipation is by far the most common complaint of those who live in cities. While the rational treatment consists in attention to the diet and other hygienic measures, for the most part, it is so much easier to read one of the innumerable advertisements which depict the terrible consequences of constipation, and the one certain means of escape therefrom, that the credulous are inclined to accept such statements as true, and, in a way, lionize themselves because of the dangers they have encountered and escaped.

Any attempt merely to enumerate the financially successful nostrums of this type involves one in immediate difficulties, because of the enormous number of those advertised to the public, while those of this type advertised to physicians are scarcely less numerous.

The principal purgative salts and their indications are so well known that we shall confine ourselves mainly to enumerating some of them, with suggestions for the forms in which they are available, and a few of the combinations which may be found useful. We shall have occasion to contrast the well-known actions of these drugs with the absurd claims made for some of the nostrums which they compose.

MAGNESII SULPHAS.—U. S.—Epsom Salt (by which name it is most widely known) is so called because it was obtained by evaporating the water of Epsom Springs. It is one of the chief constituents in many famous purgative waters, such, for instance, as the Hunyadi of Hungary.

Average dose: 15 gm. (4 drams).

MAGNESII SULPHAS EFFERVESCENS.—U. S.—(Its preparation has been detailed.)

Average dose: 15 gm. (4 drams).

MAGNESII CARBONAS.—U. S.—A bulky, white, odorless and nearly tasteless powder, which is insoluble in ordinary solvents.

Average dose: 3 gm. (45 grains).

MAGNESII OXIDUM.—U. S.—This, commonly called magnesia, or calcined magnesia, closely resembles the carbonate in its several properties.

Average dose: 2 gm. (30 grains).

MAGNESII OXIDUM PONDROSUM.—U. S.—This differs from the preceding only in being more dense, and therefore requiring a less bulky dose. It was originally known as Husband's magnesia.

Average dose: 2 gm. (30 grains).

LIQOR MAGNESII CITRATIS.—U. S.—This, almost always called "citrate of magnesia," is one of the most agreeable of the purgative preparations, but it does not keep well, and should therefore be ordered freshly prepared.

Average dose (as purgative): 360 c.c. (one bottle).

Magnesium carbonate is frequently employed as an ant-acid, the oxides, light and heavy, are ant-acid and laxative. The oxides should be given with a large excess of water. They are much used for children.

POTASSII ET SODII CITRAS.—U. S.—This is commonly called Rochelle salt because it was first manufactured in the city of Rochelle. It was discovered by a pharmacist named Seignette and is often called Seignette salt by the French.

Average dose: 8 gm. (120 grains).

LIQVRS EFFERVESCENS COMPOSITVS. U. S. Solubilis powder is the form in which Rochelle salt is most often used.

SODII PHOSPHAS. U. S. This has come into very general use of late years in the treatment of chronic constipation, and it is popularly believed to exert a special influence on the liver. It is soluble in about six parts of water.

Average dose: 2 gm. (30 grains).

SODII PHOSPHAS EFFERVESCENS. U. S. This is much more pleasant to take than the ordinary sodium phosphate, of which it contains 20 per cent.

Average dose: 8 gm. (120 grains).

SODII PHOSPHAS EXSICCATUS. U. S.

Average dose: 1 gm. (15 grains).

A preparation so well known as sodium phosphate requires no therapeutic notice, but we wish to offer some suggestions as to the forms in which it is available.

The effervescent salt leaves little to be desired when one wishes to employ it as a laxative, but it is not well adapted to use with hot water.

We give below several examples of its combinations. In some of these lithium citrate is used. Of course, these may be endlessly varied, using the dried magnesium sulphate, for instance, instead of the dried sodium phosphate.

Caffein is often given with effervescing salts, and this or other similar substances may be incorporated without materially changing the formulas.

R. Lithii citratis	3i	5/0
Sodii phosph.	3viii	30/0
Sodii bicarb.	3x	40/0
Acidii tartarici.	3vi	25/0

The dose of this is about 4 gm. (60 grains).

For use with hot water the following extemporaneously-prepared mixture is preferable to the official effervescent salt:

R. Potassii bitart.	3x	40/0
Sodii bicarb.	3v	20/0
Sodii phosph. exsic.	3x	40/0

The dose of this preparation is the same as that of the one preceding it. In case a more alkaline mixture is desired the amount of sodium bicarbonate may be slightly increased and the potassium bitartrate correspondingly decreased.

LIQOR SODII PHOSPHATIS COMPOSITVS.—U. S.—This represents 100 per cent. of sodium phosphate.

Average dose: 8 c.c. (2 fluidrachms).

To make this solution, the Pharmacopeia directs that 100 gm. of sodium phosphate and 4 gm. of sodium nitrate be triturated together in a mortar with 13 gm. of citric acid, until completely liquefied, then sufficient water is to be added to make the product measure 100 c.c.

Although this requires no more skill than the weighing of the salts, the Alta Chemical Company pretends that it thus secures "An Ideal Nerve Tonic, Laxative, Analgesic! Stimulant of Glandular Function, adjuvant to all organic remedies indicated in the organism! relieving Hepatic Congestion, supporting Sexual Power, regulating both excretion and secretion on a normal physiologic basis!"

The indications enumerated are far too absurd to repeat, but as an example of this word waste we quote the following: "Especially reliable as a painless cure for the Morphin Habit!" Does this insolent company suppose that we are bereft of every vestige of intelligence when it insists on telling us such manifest falsehoods as we have quoted, or that Rheumaggon, consisting of sodium iodid and sodium phosphate, is "a specific in all cachectic disorders!"

Surely, Baron Munchausen, in his wildest flights of fancy, never imagined anything more preposterously absurd.

When we see how simple is the preparation of the various effervescent salts, and remember that the Pharmacopeia provides reasonably high standards and readily applied tests for the purity of all official salts, with which all reputable manufacturers of chemicals comply, we see how absurd is the pretense of the nostrum makers that they have special processes and peculiar facilities for manufacturing products of superior quality.

LITHII CARBONAS.—U. S.—It is more than sixty years since Lipowit announced that this salt favored the solution of uric acid. Since then the lithium salts have been widely used, especially in combination with purgatives and diuretics, but there is no evidence that any benefits result from such combinations.

The lithium salts are of comparatively little importance according to the accepted authorities in therapeutics of to-day.

Average dose: 0.5 gm. (8 grains).

LITHIUM CITRATE. U. S.—Is used for the same purposes and in the same dose as the carbonate.

LITHII CITRAS EFFERVESCENS.—U. S.—Is a convenient form for administering the citrate.

Average dose: 8 gm. (120 grains).

Lithium salicylate was made official in 1880 because of its asserted superiority in the treatment of acute rheumatism; it possesses no advantages over the other salicylates, but the nostrum makers having seized on it while the first reports of its successful use were being circulated, they continue to make the

most extravagant claims for it in their preparations. Cushny specifically denies that the salt has any especial solvent action on uric acid in acute rheumatism; this should be borne in mind when few circular pharmacology is under consideration.

Sal-lithin is typical of a host of nostrums which consist of lithium and purgative salts. It is made by the firm which exploits the thoroughly discredited bioplasm by such absurd misstatements and reprehensible methods. (See THE JOURNAL, vol. xiv, pp. 1587-1812.)

Sal-lithin, according to the advertisement in hand, combines lithium benzoate and citrate, 12.5 per cent., with sodium phosphate and other salts. "Unequalled in Uric Acid Diathesis," "Blood Cleanser," etc. It will be perceived that we have here nothing new, nothing original, and nothing which the practitioner can not obtain from any reputable pharmacist on his own prescription independently of this Bioplasm Company.

In the same circular we find on pages 4 and 5 an invitation in most undignified language to prove the untruthfulness of the assertions made regarding bioplasm; and then in order to save one even that slight trouble (really none at all) the evidence needed is furnished in the following: "Its origin, composition, and formula is published" (the grammar is theirs), "the only reservation being its working or cultivation formula. If this debars it for any one, such are also debarrd from using all proprietary remedies, all synthetic products, or even the compounds of the Pharmacopoeia, as each manufacturer holds his carefully designed and economic working formulas as a part of his stock in trade and a secret."

This misrepresentation in regard to the Pharmacopoeia preparations is wholly gratuitous.

The number of uric acid solvents, each of which is the "most powerful known," is truly surprising. It is still more surprising that mankind continues to suffer from rheumatism and gout, nearly as much as they did before these "discoveries" were made.

Mr. J. LeRoy Webber, Ph.G., is credited by the Bristol-Myers Co. with originating sal hepatica, the really "most powerful" one. It is passing strange that so great a genius should continue to devote his time to supervising its manufacture, since any youth of common intelligence could certainly do it quite as well. This truly wonderful discovery of Mr. J. LeRoy Webber, Ph. G., is also useful, so we are told, in the treatment of "Fullness of Blood," likewise "Acidity of the Stomach," though most of us prefer some acidity of the stomach and not a little blood to all our arteries.

If further literature of a similar nature is desired, we suggest the careful reading of the *Uric Acid Monthly*, particularly with regard to the munificent offer for reports "suitable for publication."

It must be evident to the least observant that we are drifting far from the safe course in therapeutics when men, who have not sufficient knowledge to avoid these absurdities, so glaring that they become apparent on the first appeal to reason, thus exploit our profession and use us to dupe the public. Are we to continue in this degrading position or are we to assert our independence and demand common sense, at least, from those who seek to serve us? The arrogance of the nostrum vendors under the cloak of servility is become insupportable, and physicians should no longer tolerate such abuses.

While we have divided the cathartics (under which term we include laxatives) into two general classes, vegetable and saline, this has been done merely for convenience of grouping, and we shall now take up the more important laxatives and cathartics which have not been discussed.

HYDARGYRIUM CUM CRETA.—U. S.—Gray Powder.—This contains 38 per cent. of mercury (metallic) mechanically mixed with clarified honey and prepared chalk.

Average dose: 0.25 gm. (4 grains).

MASSA HYDARGYRI.—U. S.—The well-known "blue mass" contains 33 per cent. of mercury (metallic) combined with glycyrrhiza, althca, glycerin, and honey of rose.

Average dose: 0.25 gm. (4 grains).

HYDARGYRI CHLORIDUM MILE.—U. S.—Calomel is required by the Pharmacopoeia to contain at least 99.5 per cent. of pure mercurous chlorid.

There is, perhaps, no drug which is better known than calomel, and we can afford to give it space in inverse proportion to its importance.

Average dose (as a laxative): 0.12 gm. (2 grains).

Despite the widespread use of the mercurials, their mode of action remains a problem. Some authorities assert that calomel must be converted into the oxid, others that small amounts of the bichlorid are formed, and that this is the active agent. The effect on the organism is not less a matter of dispute; pharmacologists usually deny that it causes an increase of bile-flow, as experiments, made by careful observers, on both man and animals with biliary fistula have failed to demonstrate any increase. Calomel acts as an antiseptic and the bile is thus protected from decomposition, while the increased peristalsis affords less time for its absorption. Some of the older clinicians, however, still hold to the theory that it really does increase the amount of bile secreted by the liver. However calomel may act, it is the best remedy we possess for that form of indigestion and constipation which is frequently called "biliousness."

Mercury and chalk, commonly called gray powder, does not occasion so much nausea as the other mercurials in common use, and is usually preferred for children who suffer with indigestion and constipation with considerable intestinal putrefaction.

The mercurials are contraindicated in chronic conditions, such as tuberculosis, and in the latter months of pregnancy. The use of calomel as a diuretic has been mentioned, and, while Wood pronounces it useful in chronic parenchymatous nephritis, others maintain that it is injurious, and Solimann has recently suggested that great conservatism should be exercised in its employment. At any rate it should not be used merely for its purgative effect when nephritis exists, or only with great caution.

SULPHUR PRECIPITATUM.—U. S.—SULPHUR SUBLIMATUM.—U. S.—and SULPHUR LOTUM.—U. S.—Are the three forms in which Sulphur is now official. Either the sublimed or the washed may be used as a laxative. The sulphur is slowly converted in the intestine into the sulphid, only to a small extent, which acts as an irritant, while the greater part of the sulphur remains insoluble and acts mechanically—merely by its bulk. Washed sulphur is an ingredient of compound powder of glycyrrhiza.

Average dose (of any of the three forms of sulphur): 4 gm. (60 grains).

(To be continued.)

Clinical Notes

ACUTE ABDOMINAL SYMPTOMS IN TYPHOID FEVER FROM INFLAMED MESENTERIC GLANDS,

TWO ILLUSTRATIVE CASES.

SIMULATING INTESTINAL PERFORATION AND OTHER ACUTE ABDOMINAL CONDITIONS.*

RUSSELL STURGIS ROWLAND, B.S., M.D.
DETROIT, MICH.

Acute abdominal symptoms in typhoid fever have recently attracted considerable interest because of the importance of early diagnosis in intestinal perforation.¹

The literature is becoming filled with records of cases containing additions to our knowledge of diagnosis and treatment.² These studies have shown the varied symptomatology of intestinal perforation and have demonstrated that exploratory laparotomy for diagnostic purposes is more conservative than waiting, in doubtful

* Read before the Michigan First Council District Medical Society, Dec. 22, 1905.

2. McCreae and Mitchell: Johns Hopkins Hosp. Report, vol. x, Nos. 6, 7, 8, 9.

cases. As a result, an increasing number of patients have been operated on in whom no perforation was found. Almost every surgeon of experience has had one or more of these cases.³

I wish to relate the histories of two typhoid fever patients who had such pronounced abdominal symptoms that in one intestinal perforation was suspected, and in the other a complex of abdominal conditions—appendicitis, tuberculous peritonitis or typhoid fever complicated by one of these conditions. Laparotomy was performed in both instances, and in neither case was there any evidence of peritonitis, intestinal perforation or any of the other abdominal conditions suspected. The symptoms were ascribed to swollen, inflamed mesenteric glands in the region of the cecum.

I am indebted to Dr. John Lovett Morse of Boston for the privilege of reporting these cases:

CASE 1.—Typhoid fever; acute abdominal symptoms, on the thirty-ninth day simulating perforation; exploratory laparotomy; only inflamed mesenteric glands found to account for the condition.

Patient.—W. W., male, aged 26, was admitted to the Boston City Hospital May 20, 1903, on the ninth day of his illness.

Examination.—He gave an ordinary typhoid history and on admission had the usual apathy, flushed cheeks, characteristic tremulous, coated tongue, with red tip and edges, an enlarged palpable spleen and a profuse roseola. The temperature was 103 and the pulse 92. On the day following admission the Widal reaction was positive in a dilution of 1:80 in forty-five minutes, and the leucocyte count was 7,200.

Course of the Disease.—He passed through a moderately severe course of the disease, having a small rectal hemorrhage on May 29, the nineteenth day of the disease. At this time there was no complaint of pain, the abdomen was not distended, he was not restless nor delirious; his pulse was of excellent quality and not changed in rate, and the leucocyte count was 4,600.

On June 2, the twenty-third day, there had been no further rectal hemorrhage; the abdomen was not distended nor tender; the temperature was running with a wide diurnal swing and reaching a lower level.

On June 17, the thirty-eighth day, the note says "uneventful convalescence; patient now up and about the ward for three days." This indicated that the temperature had been normal for about ten days, that the diet had been increased to a simple mixed hospital diet, that the patient was doing light work about the ward and expected to be discharged in a day or two.

On June 18, the thirty-ninth day, early in the morning the man complained for the first time of "cramps in the stomach," which he said began late the day before. The pain was severe enough to keep him from sleeping, though not sufficient to make him complain to the night nurse. At 8 a. m., when seen by the house physician, he had a pale, anxious expression, a pulse in the neighborhood of 120 and a temperature of 100.6. His abdomen was moderately distended and tympanitic, with tenderness and resistance more on the right side. There was no nausea; the bowels moved freely after a soapsud enema; the dejection was semisolid, light brown and without macroscopic blood. The leucocyte count, taken at this time, was 22,100. At 11 a. m. the patient was seen by Dr. Lund in consultation with Dr. Morse. He still had the anxious expression and pallor. The pain had persisted, more severe at one time than another, and indefinitely localized in the right side of the abdomen. There was moderate distension, slight rigidity, muscular spasm and tenderness. No masses were felt and the tenderness could not be definitely localized, although at times it seemed to be more marked in the right lower quadrant. The leucocyte count remained as high as in the morning, 21,100. The temperature had dropped a little, to 99, while the pulse remained in the neighborhood of 120.

A diagnosis of intestinal perforation (?) was made and immediate operation advised. The patient was transferred to the operating room at 3:30 p. m.

Operation.—Dr. Lund made an incision two inches long under cocaine anesthesia in the right linea semilunaris, and the abdomen was opened without incident. There was no free fluid. The gall bladder was found in normal condition. At this stage exploration of the abdomen proving painful, on the patient's request, nitrous oxide followed by ether was given. Examination in the right lower quadrant, to which most of the pain was referred after opening the abdomen, revealed a mass of enlarged mesenteric glands, some of them the size of small hen's eggs. Counter abdominal incision was made, over the tumor, to determine if any broken down glands were present. Considerable congestion, but no evidence of breaking down was found. The abdominal wounds were closed in the usual way. There was a good recovery from the anesthetic.

On June 20, the forty-first day, the surgical note states that since the operation the patient has been very uncomfortable, complaining considerably of pain; his abdomen has been markedly distended, in spite of free bowel movements; there has been no vomiting.

By June 22, the forty-third day, the pain and distension had gradually decreased and there had been a steady improvement in the patient's general condition.

On July 6, the fifty-seventh day, "uneventful convalescence; abdominal wounds showing firm cicatrices; general condition good; patient anxious to go home; discharged at his own request to the surgical outpatient department."

Remarks.—In this case the abdominal symptoms developed suddenly, on the thirty-ninth day of the disease, at the end of what appeared to be a normally progressing typhoid convalescence. Pain was the most striking symptom. It developed insidiously, was not extreme, but was lasting and more severe at one time than another. It was indefinitely localized in the right side of the abdomen. Accompanying the pain there was tenderness on deep palpation, slight abdominal distension and spasm of the right rectus muscle. There were no signs of gas or fluid in the peritoneal cavity and no tumor was felt. Hemorrhage was ruled out by the free bowel movement without blood. Besides the local symptoms there was the general picture of collapse—dusky pallor, anxious expression and rapid pulse; and a marked leucocytosis. All the above facts, when considered together, made the diagnosis of intestinal perforation very probable and the exploration of the abdomen in our opinion justifiable.

CASE 2.—Typhoid fever; acute abdominal symptoms on the fifth day. Exploratory incision showed the condition to be due to inflamed mesenteric glands.

Patient.—M. L., female, aged 6, was admitted to the medical side of the Children's Hospital, Boston, on Sept. 7, 1904, on the sixth day of her illness.

History.—The history, given by the mother, was one of sudden onset with pronounced nervous and abdominal symptoms. On the day before admission the patient had complained of "pain in the stomach," and the mother noticed for the first time that her child's right leg was drawn up.

Examination.—The patient was seen in the surgical outpatient department and recommended to the house with the diagnosis, "typhoid fever or appendicitis (?) for observation."

The admission physical note states that the child was poorly developed and nourished; that her cheeks were flushed, and that her face had a pinched, anxious expression. There was photophobia, the pupils were equally dilated and sluggish in their reaction to light; the tongue was swollen and covered with a heavy white fur; the heart was not enlarged, was regular and rapid in action with sounds of good character; there were normal resonance and breathing throughout both lungs. Examination of the abdomen showed slight distension, with moderate tympany and general tenderness, more marked on the right side, where an irregular mass could be felt, below McBurney's point. There was considerable spasm of the muscles in the right lumbar region, the right thigh was drawn to one-third flexion, and the tendon reflexes were increased. Blood examination showed a hemoglobin of 85 per cent, and a leucocyte count of 13,800.

Course of Disease.—September 8, the seventh day, on the morning following admission, the record states that the patient had been very irritable and restless, crying out in delirium and also sharply when disturbed, but making no complaint at other times, although she appeared to be in pain. She had taken small amounts of nourishment without vomiting; the bowels had moved freely following a soap-suds enema. At the time of the examination she lay with eyes closed and right leg flexed. There was a pained expression and dusky pallor; the pupils were equal and reacted to both light and accommodation; there was rigidity of the neck and extremities, probably voluntary. Examination of the ears was negative. There were a few squeaky râles at the base of both lungs; the heart action was rapid, and the sounds were of good character; the abdomen was flat, lax and slightly more resistant in the right lower quadrant, where a freely movable tumor of the size of a walnut could be felt. The tenderness was more marked in this region, and there was evident pain on pressure over the mass, psoas spasm was considerable, motion at the right hip was limited and apparently painful. Rectal examination revealed a bulging, resistant mass, on the right, similar to that felt by abdominal palpation. The child was delirious and semi-comatose so that statements about pain were not reliable. The temperature ranged in the neighborhood of 105; the pulse was over 140. The urine was high colored, acid in reaction and had a specific gravity of 1015; there was a trace of albumin, no sugar and a few renal elements. The leucocyte count continued about the same, 13,400. The Widal reaction was reported negative, as would be expected, on the seventh day of this disease.

Operation.—The patient was seen by Dr. Stone, in consultation with Dr. Morse, and abdominal exploration was advised. The diagnoses made at this time were, in order of preference, appendicitis, tuberculous peritonitis or one of these conditions complicating typhoid fever.

The operation was performed by Dr. Stone. Ether was administered and the abdomen was opened by the "usual appendicectomy incision." The tumor was found to be a mass of enlarged, congested mesenteric glands, several of which were the size of walnuts. There was no evidence of perforation, peritonitis, or breaking down of these glands. The Peyer's patches were injected and thickened, as is usual in typhoid fever. The appendix was slightly congested as a part of the typhoid picture. The abdomen was closed without further operative interference. There was a good recovery from ether.

Postoperative History.—The child was restless and delirious during the night following the operation, but responded fairly well to stimulation. The temperature remained high and the pulse rapid, ranging between 160 and 170.

On September 12, the eleventh day, the patient continued weak and irritable, crying out sharply at times in delirium. She had no nausea and did not vomit, but had to be forced to take her nourishment. She had begun to show emaciation with a sunken appearance about the eyes; the respirations were rapid, out of proportion to the temperature and changes in the chest. The abdomen was very slightly distended and tender in the region of the wound. The leucocyte count was 5,200; the Widal reaction was positive in a dilution of 1-80. The urine was acid, cloudy, yellow and with a specific gravity of 1022. It contained a trace of albumin and a strongly positive diazo reaction; sugar was absent.

The patient passed through a severe course of the disease with profound toxic symptoms and a complicating otitis media.

On October 8, the thirty-fifth day, the clinical note says: "Improvement slow, temperature staying down; patient very weak, unable to sit up but for a few minutes at a time." She showed considerable emaciation and still had a purulent discharge from the right ear. The pulse was of good character and the appetite was improving.

On October 22, the forty-ninth day, the patient had gained sufficiently in strength so that she was "discharged relieved to the Convalescent Home."

Remarks.—The abdominal symptoms in this case occurred early, on the fifth day, in the course of a severe typhoid. At this time there was no roseola; the spleen was not enlarged

and could not be felt; the Widal reaction was negative; the heart action was rapid, instead of being relatively slow; there was a moderate leucocytosis; all of which made the diagnosis of typhoid uncertain. The presence of a tumor in the right iliac fossa still further complicated matters so that the real state of affairs never once suggested itself. Appendicitis was the preferred diagnosis of the physician as against tuberculous peritonitis of the surgeon, with in either case possibly a complicating typhoid fever. The diagnosis of tuberculous peritonitis was influenced by a history of failing health for the past two years.

The striking feature in the case was the tumor. If this mass had not been felt the condition might very well have been taken for perforation and peritonitis, as in the first instance. In regard to the other local symptoms, they were obscured by the intensity of the general nervous condition; however, the impression given was that there was a constant, severe pain, which was paroxysmal in character, localized in the right iliac region, the region of the tumor. How much the local symptoms influenced the general condition could not be determined.

As frequently happens after a diagnosis has been made positive by exploration, the question came to us: "Why did not we think of that before?" Those of us who had seen both cases were immediately struck by their similarity and convinced that the symptoms were due to the inflamed, mesenteric glands. We had the feeling that we might have diagnosticated the second case correctly and would certainly try to differentiate the condition in the future.

That acute abdominal symptoms simulating intestinal perforation and peritonitis could occur during the course of typhoid fever from swollen, inflamed mesenteric glands, has been thought probable for some time; definite statements in the literature on this point, however, are very few. Berg⁴ says that it is not uncommon for patients to develop all the clinical manifestations of a localized peritonitis at sometime in this disease. It is his belief that in some instances these symptoms may arise from stretching of the peritoneum by swelling of the mesenteric glands. Armstrong⁵ reports opening the abdomen in two cases without finding a suspected perforation. In one patient no cause was found; in the other he considered the symptoms to be due to swollen mesenteric glands. In discussing Armstrong's paper, Billings⁶ remarked that pain and other symptoms simulating perforation might be due to inflammation and infection of the glands of the mesentery. McCrae,⁷ in his analysis of abdominal pain in 500 cases of typhoid fever, states that in 70 cases in the series there was no known cause for the pain. Fourteen of the patients besides pain had local abdominal symptoms simulating perforation. Two of these patients died, both apparently of intense toxemia, and at autopsy no cause could be found for the acute abdominal symptoms, unless they were due to enlarged mesenteric glands. Abdominal pain has been described as occurring with suppurating mesenteric glands of typhoid fever, but whether the ordinary enlarged glands can give rise to pain, he says, is a question. Finally, Wilson⁸ mentions having seen several cases of sudden intense pain on the right side of the abdomen in the iliac region with rigidity of the muscles and but very little constitutional disturbance. In a few hours these symptoms passed away and the patient was left apparently as well as previously. He was at a loss to account for the condition, which is certainly suggestive in this connection.

There was no doubt as to the cause of the acute abdominal symptoms in our cases. In the first patient, previous to opening the abdomen, the symptoms were more on the right side; and on exploration, the pain was definitely referred to the enlarged glands in the ileocecal region. In the second case, although there was profound depression of the nervous system, it was evident that the local abdominal symptoms were associated with the large mass of glands in the ileocecal region.

LeConté² has recently reported a case of ruptured suppurating mesenteric glands occurring during typhoid fever with symptoms simulating intestinal perforation. He reviews the other reported cases and discusses the anatomy and pathology of these glands in typhoid fever. His studies show that it is the ileocecal group of glands, as in the present cases, in which there is the greatest change and enlargement. He finds that the breaking down of these glands is a rare condition; there were but six reported cases at the time his paper was written (1904). Enlargement of the glands, sufficient to produce subjective and objective symptoms, is probably much more frequent. The enlargement itself is an almost constant lesion in typhoid fever. In over one-third of the exploratory laparotomies for suspected perforation, no cause was found to account for the symptoms. With the exception of the instances already mentioned, no statement was made in regard to the condition of the glands of the mesentery; consequently, nothing definite can be said as to the frequency of acute abdominal symptoms from this cause.

Without going into a detailed account of symptoms, a few points can be emphasized which might differentiate intestinal perforation. Of first importance, it seems to me, is the presence of a tumor in the right lower quadrant. There may be fullness and tenderness in intestinal perforation on rectal examination, but a freely movable, tender mass in this region ought to suggest something more. In our second patient such a mass was easily felt. It led us to consider appendicitis and tuberculous peritonitis. In the first case there was no record of a tumor, but from the size of the mass of glands and the state of the abdomen, we were almost certain they could have been palpated. Examination should be made both by abdominal and rectal palpation in every case of this sort. Symptoms due to gas and fluid in the peritoneal cavity, obliteration of liver flatness and flatness in the flanks occur late or not at all in most cases of perforation. Of earlier occurrence in some instances is the arresting of peristalsis and spasm of anterior abdominal muscles producing a splinting effect resulting in the pushing up of the lower border of the liver. As would be expected in the two cases in question, none of the above signs was present. There was but slight distension, no change in the area of liver flatness, no flatness in the flanks and peristaltic movements persisted. General constitutional symptoms are very variable in cases of perforation, but usually there are signs of shock followed by the collapse of general peritonitis. In our two cases the symptoms were more those of severe toxemia.

It is of interest to note in this connection that symptoms due to swollen mesenteric glands may occur early in the course of typhoid fever, in the first instance on the thirty-ninth day, and in the second on the 41st day of the disease.

Elberg,³ in discussing the indication for operation in intestinal perforation, has made the statement that

when the symptoms have been at least of twelve hours' duration and the signs and symptoms point more to perforation than anything else, especially if the patient's general condition is growing worse, operation is justifiable. In both cases the pain and local symptoms had persisted for more than the above time limit, the general condition had grown progressively worse, and from our physical examination we were not satisfied with the state of the abdomen. While believing that needless exploration should be avoided, as far as possible, we felt justified in our advice in these cases. If in the course of typhoid fever there are acute abdominal symptoms especially localized in the right lower quadrant, and a freely movable tumor can be felt there, it would seem safe to adopt an expectant plan of treatment. On the other hand, if there is any doubt, as there usually will be, immediate exploration should be advised, as the danger of operation is slight, bearing out Munroe's⁴ statement: "Exploration where there is no peritoneal infection or serious organic lesion is practically harmless."

CONCLUSIONS.

The following conclusions may be drawn:

1. In some of these cases in which exploration showed no cause for the symptoms, these were probably due to changes in the mesenteric glands.
2. Some of the recoveries which have been reported from intestinal perforation without operation probably occurred in cases of this sort in which the symptoms simulated perforation.
3. McCrac's suggestion that pain and acute abdominal symptoms might be due to enlarged mesenteric glands is credible, and further observation and study will probably show that this condition is not, relatively speaking, a rare complication in typhoid fever.

FIBROMA OF THE NASOPHARYNX.

TRACHEOTOMY, EXTERNAL CAROTID LIGATION,
EXTIRPATION, CURE.

CHEVALIER JACKSON, M.D.
PITTSBURG, PA.

History.—S. D., male, aged 14, gave a history of an increasing nasal stenosis of a few years' duration. Several pieces of a "polyp" had been removed by physicians at different times, followed in each instance by severe hemorrhage, but with no relief to the breathing, which grew worse until scarcely enough air to sustain life could be inspired, even with the mouth widely open. His parents feared he would choke to death at night, and he was awakened by a choking sensation every time he fell asleep. Death from inanition threatened because of increasing dysphagia. Bleeding had been frequent, and a week before admission a severe hemorrhage from the nose and throat almost exsanguinated the boy. Headache and earache were frequent and severe.

Examination.—The boy was frail, emaciated, pale and anemic. Leucocytes were increased; hemoglobin was decreased. Nasal respiration was impossible; his mouth was never closed except to swallow, which was difficult. The right nasal chamber was occupied by a hard tumor, which pushed the septum over tightly against the outer wall of the other nasal fossa, thus completely occluding both. The right upper maxilla was bulged outward as if by an intral tumor. The velum was pressed forward on to the tongue, with which it was in contact at all times, except when lifted by a semi-voluntary effort at each inspiration. Back of the tightly stretched velum a smooth, hard, glistening, reddish, vessel-streaked tumor filled the nasopharynx so completely that the finger could not palpate any but the visible portions of the growth. Diplopia and exophthalmos showed the bulging upward of the orbital plate.

Operation.—A clinical diagnosis of fibroma was made, my opinion being that it was bi-lobed and that it had its origin on the right side of the vault close to the right choana, all of which proved to be correct. General anesthesia in such a case is practically impossible. Respiratory arrest is synchronous with unconsciousness. Dr. John W. Boyce very kindly infiltrated an area over the trachea, which enabled me to open the trachea in a few minutes absolutely without pain. This was remarkable in a frail boy, who was watching our every movement. Chloroform was now skillfully administered through the tracheal wound by Dr. W. H. Strang. The right external carotid artery was ligated between the lingual and the superior thyroid arteries to forestall hemorrhage. A small probe, in whose point a small eye had been drilled, was threaded with braided silk and passed backward through the right nasal chamber. It was insinuated between the growth and the tightly stretched velum, through which it could be felt as it worked backward. When the eye point of the probe reached the free margin of the velum, the silk was caught with forceps and drawn out the mouth for a convenient length and the probe was withdrawn from the nose. The bight of a length of snare wire was tied to the nasal end of the silk, by means of which the wire loop was drawn back through the nose until it reached the pharynx. The loop was then insinuated around the presenting portions of the growth and worked upward by traction on the ends projecting from the nose. When the loop was felt to be taut around the base of the growth, these projecting wire ends were threaded through the straight canula of a Peters tonsil snare by my assistant, Dr. Ellen J. Patterson. Closing the snare handles, the growth was cut through at one stroke. The severed tumor was then delivered with strong forceps, without lacerating the palate, though this seemed imminent, owing to the tight fit of the growth.

The bleeding was about as much as from an adenoidectomy: nothing like the swelling up after the extirpation of a fibroma. Anterior and posterior plugs were placed and the tracheal canula which had been inserted to facilitate anesthesia was removed as soon as the boy came out sufficiently. The plugs were allowed to remain forty-eight hours. No bleeding followed their removal.

The temperature rose to 101 F., but returned in two days to normal. The carotid wound healed promptly. The boy was out of bed on the third day, and was discharged well at the end of the week. No sign of pulsation was yet perceptible at the temporal artery two weeks later.

The right upper maxilla had undergone a pressure atrophy which had almost obliterated the antrum. There was no cartilage in the septum, probably also the result of the same process, and the nasopharyngeal cavity was enormous. The growth, which weighed 1,270 grains, was found by Dr. Ralph Duffey to be a pure fibroma.

When one looks over the appalling list of deaths on the table from hemorrhage in the removal of fibromata and over the list of preliminary operations, temporary and permanent jaw resections, etc., the contrast here recorded seems to furnish food for thought. I have ligated the external carotid artery thirty-four times without in any case an untoward result. Eight of these ligations have been preliminary to the extirpation of nasopharyngeal fibromata, and in no instance has the bleeding been serious. The greatness of the contrast can be realized only by one who has seen the blood well up out of the mouth like water out of a drinking fountain. External carotid ligation is a guarantee against hemorrhage, shock and collapse. Not only does it prevent loss of blood, but by diverting a greater quantity of blood into the internal carotid it increases intracerebral blood pressure. Whether this agrees with the physiologists' dynamics of blood pressure or not I do not know, but clinically I have seen throbbing headache and also insomnia of a few days' duration follow external carotid ligation, and I have seen no shock in eight cases of extirpation of nasopharyngeal fibromata, cases similar to

ones in which death occurred from hemorrhage and collapse. In my opinion, these observations point to increased intracerebral blood pressure after the ligation. The influence of local anemia in the prevention of recurrence is, of course, an additional advantage, especially in cases of double ligation, or, better still, excision.

I do not consider an operation for true fibroma of the nasopharynx justifiable without preliminary ligation of one or both external carotid arteries. If the side from which the growth springs can not be determined, ligation of both external carotids is indicated, preferably with an interval of three or four days, during which the tracheal wound may be kept from healing by packing with gauze wrung out of mercuric bichlorid solution, no tube being worn and no air being permitted to pass through the wound. From this there is no danger of pneumonia. Nor do I consider it justifiable to administer a general anesthetic until after the trachea has been opened, if the growth be large enough to press the velum forward on to the tongue. I do not say that neglect of these precautions means death, but I claim that the mortality of these operations can be thus reduced practically to naught. Hemorrhage, dyspnea and chloroform act synergistically in the induction of collapse. Let us forestall hemorrhage by external carotid ligation and dyspnea by tracheotomy (under local anesthesia) so that we may give our chloroform in comparative safety.

METHOD OF WASHING SMALL PIECES OF TISSUE.

GUTHRIE MCCONNELL, M.D.
ST. LOUIS.

I have devised a method of washing small bits of tissue which have been hardened in Zenker's or similar fluids, and which does away with the difficulties usually encountered in that proceeding.

As shown in the accompanying illustration, a piece of fine-meshed copper wire netting is rolled into a cylinder and stuck

well down into a bottle. The bits of tissue are put in this and the water is turned on; all danger of losing the specimen is obviated as the water can not rise to any degree above the mouth of the bottle.

Until I happened to think of this method I had to devise rather elaborate or cumbersome ways of accomplishing the desired end.

SATURDAY, FEBRUARY 17, 1906.

THE NATURE OF ENZYMES.

Since up to the present time no ferments have been isolated in an absolutely pure condition we are entirely unfamiliar with their chemical characters, and consequently are obliged to recognize them solely by their action. So far as we know, true enzymes never occur except as the result of cell life—they are produced within the cell and increased in amount by each new cell that is formed, and, furthermore, they are probably present in every living cell without exception. As the same facts are equally true of the proteids, and apparently true of nothing else, it is natural to associate the enzymes with proteids and so to explain the importance of the proteids for cell life. If enzymes are obtained in any of the usual ways from animal cells or secretions they are always found to give the reactions for proteids, even if repurified many times; but it is well known that by any method of precipitating proteids the other substances in the solution tend to be dragged down by the colloids, and it is possible that the enzymes are merely associated with the proteids in this way. Furthermore, enzymes are known to become so closely attached to stringy protid masses, such as fibrin and silk, that they can not be removed by washing. Some observers have claimed that they have secured active preparations of pepsin and invertase that did not give protid reactions and contained very little ash or carbohydrate, but it has so far been impossible to secure trypsin free from protid, and diastase seems to be an albumose-like substance. Analyses of enzymes purified as completely as possible do not have great worth, for these substances are probably far from pure; however, it is of some importance that they vary greatly in the proportions of carbon, hydrogen and nitrogen which they contain, indicating that possibly different enzymes may be of very different nature. Active gum enzymes, with oxidizing properties, are said to have been prepared free from nitrogen.¹

Macallum has shown microchemically that phosphorus is closely associated with the formation of zymogen granules in cells, which seem to be started in the nucleus, and there are many other observations suggesting that certain ferments are closely related to the nucleopro-

teids. This is particularly true of the oxidases, which seem also to contain iron and manganese. A final point of importance in support of the protid nature of enzymes is that pepsin destroys trypsin and diastase, while trypsin destroys pepsin.

So uncertain, however, is our information concerning the chemical nature of the enzymes that it has become possible for a hypothesis to be developed urging that enzymes are immaterial, that the actions we consider as characterizing enzymes are the result of physical forces which may reside in many substances, and perhaps even free from visible matter. Arthus, who has been the chief champion of this very interesting conception, compares enzyme action to such forces as magnetism. A magnetic iron bar loses its characteristic property when sufficiently heated just as an enzyme does. Dissolve either the magnet or the enzyme in strong hydrochloric acid and it loses its power to affect other substances. It has been equally impossible to isolate enzymes and magnetism, both of which are recognized by their actions and not by themselves. Just as light, heat and electricity were once considered as matter, so has it also been with enzymes, and Arthus believes that they will eventually be stricken from the list of material things and considered as forms or a form of energy. There can be no question that this conception rests on strong grounds, and it possesses the stimulating qualities that make an hypothesis helpful, but, as Oppenheimer says, all chemical substances may be considered in the same way. We recognize all bodies through some form of energy; if we speak of sulphuric acid it is really of the properties of energy it shows, such as its taste, which is the energy imparted by its ions to the nervous system, or its combining with bases, etc., which also is a manifestation of energy. In the same way we recognize the ferments, and we may properly believe that they are fully as definite substances as is sulphuric acid. The magnet comparison also fails when we remember that the magnetism can be introduced into a bar of iron and removed at will, but as yet it has not been possible to introduce enzymatic properties into an inert protid or to restore them to an enzyme that has been destroyed by heat.

Other valuable evidence of the material existence of enzymes is their specific nature, lipase affecting only fats, and trypsin only proteids, indicating chemical individuality. They are true secretions, formed within the cell by recognizable steps, and, furthermore, when injected into the body of an animal they give rise to the formation of specific immune bodies that antagonize their action. Emil Fischer's work with the sugar-splitting enzymes, moreover, indicates that they owe their action to their stereochemical configuration. He prepared two sets of sugar derivatives which differed from each other solely in the arrangement of their atoms in space (i. e., isomers) and found that one specific enzyme would split members of only one of the sets, while another would act only on the variety with the

¹ A recent paper by Tschirsch and Stevens casts considerable doubt on this statement. *Pharmac. Centralblatt*, 1905, vol. I, p. 101.

opposite isomeric form. These experiments make it very probable that there must be a certain relation of geometrical structure between an enzyme and the substances it acts on, and leaves little room for question of its material nature.

Bredig has found that colloidal solutions of metals have many of the properties of true enzymes, accomplishing many of the decompositions produced by enzymes, being affected by temperature of nearly the same degree, and even being "poisoned" by substances that destroy or check enzymes. The only possible explanation of these phenomena seems to be that the effects are brought about by surface phenomena. A colloidal solution of platinum, so far as is known, differs from a piece of metallic platinum solely in the enormously great amount of surface it offers in proportion to its weight, and it is well known that surface may affect chemical action. Hence we have the possibility that some enzyme actions at least may depend on the existence of a very large surface, and since by no means all colloids are enzymes, that this surface must bear a certain relation in form to the surface of the body that is to be acted on.

COPPER SULPHATE INSUFFICIENT FOR WATER PURIFICATION.

We have referred several times to the claim made in some quarters in behalf of copper sulphate as a means of ridding water, not only of obnoxious algae and infusoria, but of pathogenic bacteria as well. In so doing, we expressed hesitation about accepting, on the evidence then available, the doctrine that the addition of a few pounds of copper sulphate to a large body of polluted water was sufficient to free the water from dangerous germs. It now appears that this conservative attitude was fully warranted. A series of important investigations carried out on this subject under the auspices of the progressive State Board of Health of Massachusetts have just been published,¹ and serve to shed a good deal of light on points heretofore obscure. It is shown that not only is the use of copper sulphate in water filtration not an aid to purification, but that, on the contrary, when the salt is applied directly to the water on the surface of a filter, it reduces the efficiency of the filter very materially, and eventually would seriously impair the essential biologic action of the filter. In accordance with the thorough-going methods of the Massachusetts Experiment Station, this statement is based on experiments lasting for a full year.

A prolonged experimental investigation on the bactericidal action of copper is also reported in the same connection. The important conclusions here reached as the results of extended experiments are notably different from those based solely on a small number of tests made with limited quantities of water in a laboratory.

The writers (Clark and Gage) "believe that the treatment of water with copper sulphate or by storing in copper vessels has little practical value." Their principal reason for this conclusion is that although the removal of *B. coli* and *B. typhosus* is occasionally accomplished by dilute solutions of copper sulphate, these organisms may both live for many weeks in water containing copper sulphate in greater dilutions than 1 to 100,000; and in order to be safe, dilutions of 1 to 1,000 must be used, in which case the water becomes repugnant to the user because of its strongly astringent taste. As regards the standing of water in copper vessels, the time necessary to effect complete sterilization is so long that a receptacle of almost any other material would seem to be as effective as copper. Metallic copper seems to have little more "germicidal power" than iron, tin, zinc or aluminum. The writers add: "In some instances very dilute solutions of copper sulphate or colloidal copper absorbed from contact with clean metallic copper, appear to have a decidedly invigorating effect on bacterial activity, causing rapid multiplication, when the reverse would have been true had the water been allowed to stand the same length of time without any treatment."

Whatever proves to be the merits of the application of copper sulphate to the water of reservoirs infested with malodorous algae—and there is reason to think that success will attend the method in this field—there is no good ground for the assumption that sewage-polluted water can be made pure by the addition of this chemical.

THE CENTENNIAL MEETING OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK.

In the two last numbers of THE JOURNAL may be found some account of the proceedings of the Medical Society of the State of New York during the recent meeting in Albany. The occasion is of such importance, however, especially certain features of this annual session, that it is a matter of marked interest to the entire profession. The arrangements to celebrate appropriately the one hundredth anniversary of the foundation of the society had been perfected and were carried out in the most fitting and interesting manner. The address of the president, Dr. Joseph D. Bryant, treated in felicitous manner the history of the society, the disruption of twenty years ago, and the recent cordial union of the two state organizations into one great society. One of the principal addresses of the occasion was by ex-President Cleveland, who is also a former citizen and ex-governor of the State of New York. Appropriate addresses were also made by Dr. William H. Welch of Baltimore and Dr. William W. Keen of Philadelphia. Elaborate addresses on medicine, surgery and sanitary science were prepared, respectively, by Dr. Samuel B. Ward of Albany, Dr. Roswell Park of Buffalo and Dr. Herman

1. Supplement No. 2, 1906, Journal of Infectious Diseases, p. 172-209.

M. Biggs of New York. It was regretted by all that Dr. Roswell Park, on account of illness, could not be present. His address was read by Dr. Hopkins of Buffalo. The extent and excellence of the scientific program was not impaired by the centennial proceedings, the papers and discussions being of the usual high standard of the society.

The feature of the meeting, most interesting to physicians generally, was the cordial greeting and fellowship of those who so long had been separated by rival state organizations. The full attendance on the scientific sessions, the brilliant annual dinner, which filled the large hall to overflowing, attested the completeness of the reunion.

Immediately following the address of the president of the society, the President of the American Medical Association, Dr. L. S. McMurtry of Louisville, made a brief address, expressing the gratification of the entire profession at the unification of the profession in the Empire State, and cordially welcomed the society on its resuming its place as the constituent branch of the national Association in New York. The proceedings throughout were marked by the most cordial spirit of co-operation, which assures for the reorganized society a new era of professional and scientific advancement.

The universal satisfaction and pleasure arising from the success of this memorable meeting were marred by the sudden illness, terminating fatally a few days later, of Dr. George Ryerson Fowler of Brooklyn. One of the foremost of American surgeons, and a man of attractive personality, he had devoted himself zealously to the harmonious union of the two societies. As a member of the conference committee of the society he contributed largely to the result attained. As chairman of the centennial committee he labored early and late to promote the success of that celebration. His severe illness came on suddenly at Albany on the very eve of the meeting, and elicited throughout the anxious sympathy of his colleagues.

OPPOSITION TO ORGANIZATION: WHY?

Until a few years ago the medical men of this country have practically gone each his own way; medical societies or associations have been few and far between and of small membership. Now that physicians are coming together and are striving for the common good, and a spirit of association and comradeship and betterment is abroad in the land, we begin to see what the barren years have produced. We find that unscrupulous manufacturers have amassed fortune after fortune by exploiting nostrums through the medium of our divided profession. We find nostrums by the score lauded to the skies in medical journals owned or controlled by the nostrum manufacturers. We find thousands of physicians depending on the one-sided and often untrue statements furnished them by the interested manufacturers—practically getting their "education" in therapeutics from

the trade "literature" of the proprietary medicine manufacturer. The nostrum evil and many others have come on us because of our ignorance, our lack of association in work.

There are always scavengers and carrion birds, and naturally there are commercial interests that are working against harmony and unity in the medical profession, for they see that harmony means association in work; association in work means enlightenment and knowledge, and, together, these mean an end to their dishonest and ill-gotten gains; for they grow rich on professional ignorance and the blind credulity which results. The manufacturers of worthless nostrums do not wish to see "Unity, Peace and Concord" in the medical profession. They are opposed to the rapid spread of organization—to the association in work which follows activity and harmony in county medical societies. Also, and naturally, many of the "medical" journals of the country, which can live only on the advertisements of worthless nostrums, do not contemplate this spirit of organization with any degree of pleasure. Some are openly and crudely attacking and opposing either local or state organization, or the efforts of the American Medical Association to encourage it. Others, more subtle, more wily, and hence more dangerous, are appealing to the "independence" of the individual physician; are flattering his own "individual judgment," and telling him he is too wise to allow himself to be "herded" into an organization that is "controlled by machine politicians." This sort of thing is to be expected, and unless we know the actual reasons, the real dishonest motives for such biased or untrue statements, we can not understand them. Association, work, study, enlightenment, will rapidly disclose the predatory hand of the nostrum maker, and we will realize why he is opposed to any and all organization that will bring physicians together for their own betterment and his loss through the disclosure of his lies.

These are things that each one of us should carefully consider: If we give no thought to ourselves, to whom shall we turn? If "independence" brings with it ignorance, strife and poverty, where is the advantage over association in work with the betterment, mental and financial, that results from harmony and study and that friendly feeling toward one's fellows which we find in the healthy, active county medical society? What can anyone of us "sacrifice" by associating with his fellow-physicians in a county medical society? Is there any loss of dignity or of independence in trying to become better informed, better educated, more up to date?

TWO DEFINITIONS OF MEDICAL PRACTICE.

Two judges in New York have recently given definitions of the practice of medicine. One alleged definition was by Justice Joseph M. Deuel, of the Court of Special Sessions, whose character was recently exposed by the evidence brought out in his unsuccessful suit for libel

against the editor of *Collier's Weekly*. The decision, to which we referred last week, was in the case of an osteopath who had been prosecuted by the County Medical Society and fined for practicing without a license. Judge Deuel decided, on appeal, that the practice of medicine consists of three things: Diagnosis, the discovery of the cause of disease, and its cure by drugs. According to this decision, if a physician does not prescribe drugs he is not practicing medicine. He added that the statutes aim to suppress the ignorant and indiscriminate administration of drugs, and that this is practically the whole intent of legislative medical regulation. Needless to say, if this were true, then most of the quacks and charlatans might continue their imposition on the public without let or hindrance. They might do everything, apparently, even surgery, without fear of disturbance, provided only they did not prescribe medicine, yet this is the narrow view still held by some judges.

Fortunately for New York and the work of the County Medical Society in the suppression of quackery, the other definition of the practice of medicine recently made is eminently satisfactory. Judge Greene, of the city court, said that he had looked over the legal authorities of the state without being able to find a definition of what constitutes the practice of medicine. The case before him was one that absolutely demanded such a definition for its decision. Judge Greene defined the practice of medicine as "the exercise or performance of any act by or through the use of any thing or matter or by things done, given or applied, whether with or without the use of drugs or medicine and whether with or without fee therefor, by a person holding himself or herself out as able to cure disease, with a view to relieve, heal or cure, and having for its object the prevention, healing, remedying, cure or alleviation of disease."

This definition ought to be of great value to the New York County Medical Society in its future prosecutions of illegal practitioners. It leaves very few loopholes, if any, through which they can escape. It would still be desirable to obtain an indorsement of this definition in a decision of the highest courts, but the fact that it has been given out judicially is, in any case, a useful step in advance. We believe that a rational interpretation of medical practice acts would warrant a similar definition in every state where such acts exist. As a lay journal very well says, "the person who undertakes to do the work of the doctor, which is the curing of diseases, does not evade responsibility by any trick of method. Whether there be administration of drugs, the laying on of hands, resort to bread pills, baths, dieting, blue glass, incantations or hypnotism, the operation is the practice of medicine, in the spirit of the statute. This statute is for the protection of the public health, as well as to guard the credulous invalid from the rapacity of swindlers. Judge Greene's view will be accepted as the popular view, not only because it upholds a benign law, but because it is the expression of plain common sense."

THE ADVANTAGES OF NATIONAL QUARANTINE.

Dr. Sexton's article in this issue of *THE JOURNAL* points out some of the advantages of a national quarantine over the present unsatisfactory systems adopted by the several states. The experience of last year was, in fact, an efficient object-lesson. It was not until the United States authorities took a hand that the epidemic was stayed and a miniature war between the states averted. His article, however, gives in useful detail some of the advantages as they appear to one who is on the ground and can speak from experience. As he says, the protection from disease is as important as the protection from a foreign foe, and we certainly would not leave the latter, with its expenses and perils, to be exclusively a function of local border authorities. There is much in the argument that the whole country should share the cost of the defense, although it may be certain sections are not directly threatened. The lack of uniformity of local quarantines is also a self-evident drawback to their efficiency, all the more so when, as was the case last summer, obsolete and inefficient measures are depended on in some quarters as against the more efficient ones in others. The general respect which is shown to national authority without regard to state boundaries is also a very important additional factor of efficiency. The unnecessary interruptions of commerce between the states due to whims of local health authorities is another self-evident evil which, touching, as it does, the pocket nerve, should be a strong argument in favor of national control where perhaps others might fail. Local political influences, moreover, can, as he says, be put out of the question as factors of inefficiency, a reform which Dr. Sexton deems imperatively needed. Under the Public Health and Marine-Hospital Service or under control of Army and Navy medical officers, such conditions need not exist. Whether all the states will willingly surrender their independent control of local quarantine matters may be questioned, but there is no doubt that it would be to their best interests to do so.

THE HOT SPRINGS DECISION.

Some little time ago an Arkansas judge issued an injunction against any interference with a Hot Springs touting doctor, holding that the State law prohibiting such practices was unconstitutional and that the cession of the jurisdiction of the Hot Springs reservation to the General Government was also void. The case was promptly carried to the Arkansas Supreme Court, which has just rendered its decision. It says, as regards the jurisdiction of the United States and the right of Congress to enact laws regulating the use of the Hot Springs by physicians, that it raises a question in which it would follow the decisions of the Federal courts and which it does not feel bound to consider at the present time. If the United States jurisdiction did not exist, however, there would still be a valid state law against the practices of drumming or touting for patients, and the fact that the individual in question is being prosecuted in the Federal courts instead of in State courts would not justify the issuance of the injunction. The main question with the supreme court was whether or

not the state law is valid, and it decides that it is. The judgment was reversed, with an order to dismiss the complaint for want of equity. Our reputable confrères in Hot Springs are to be congratulated and commended for their energetic conduct in this matter. The drumming system at Hot Springs had become almost a prescriptive right and the reputation of the well-known watering place had suffered accordingly. The worthy practitioners there and the public generally have long felt the reproach, but could do little to remove it. It seems to us that the supreme court's decision, in the form in which it is given, fairly settles the question and should be effective in eradicating disreputable practices and practitioners from that popular health resort.

THE COST OF ANTIVACCINATION.

At the present time there seems to be a sort of recrudescence of agitation against vaccination all over the country, but more pronounced in certain sections. This has been especially the case in Pennsylvania, where smallpox has prevailed to some extent and where, in consequence, the vaccination and isolation laws have been more strictly enforced than in ordinary times. In view of the attempts to influence public opinion and to bring about legislation for the repeal of compulsory vaccination laws, the commissioner of public health, Samuel G. Dixon, makes public some statistics and estimates of the state health authorities. From a careful estimate it appears that, outside of the cities and boroughs, the average cost of quarantining smallpox cases is, at the lowest figures, \$350 for each individual patient. Special figures are given for special localities which, in a general way, bear out these statements. In the cities or boroughs the figures are also formidable, in spite of the better facilities for isolating and quarantining these cases. For example, in a recent small epidemic at Williamsport, the public expense for caring for 18 cases was \$5,132, or \$281 apiece, while the cost of public vaccinations was only 29 cents apiece. These figures could probably be paralleled in many other states and communities where smallpox has prevailed, and ought to be of some influence with the taxpayers and legislatures. If a fraction of the cost of smallpox could only be assessed on those who are responsible for it, viz., the antivaccinationists, there would very soon be an end to their arguments and agitation. It is a disgrace to civilization that in any modern community of presumably civilized people such a wholly preventable disease as smallpox should exist, and a still greater discredit to their intelligence that they should oppose the one undeniably efficient preventive of its occurrence.

CHILD LABOR REFORM.

Although the evil of child labor in factories or shops is apparently on the increase in certain sections, especially in the South, much encouraging progress is reported. Action on the subject was taken in twelve out of thirty-nine state legislatures last year, and existing laws are being enforced in a number of sections of the country. The temptations to neglect their enforcement

are great, the plea of poverty being often effective. The ultimate fact, however, remains in all cases that to make good citizens we must begin in childhood, and that any interference with the child's physique or moral welfare is a wrong that can not always be repaired—certainly not under the continuance of conditions which exist in factories, coal mines, etc., where children of comparatively tender age are too often largely employed. The medical profession should guide public opinion and take an active interest in all movements for a rational enforcement of child labor laws and their extension to states where they do not now exist. Under present conditions child labor is demoralizing morally, as well as crippling mentally and physically. If a child can not always secure its right to be well born (and that is a matter in which as physicians we are professionally interested) we are still more responsible in securing for it reasonable chances during the critical periods of growth. In some of its phases the labor question is a serious matter as far as childhood is concerned.

AN EXPERIMENT IN SEASICKNESS.

Seasickness is not generally considered a serious disorder, and its victims do not get the sympathy they deserve, considering the amount of human happiness that is even temporarily destroyed. Occasionally, however, it is a very serious matter to individuals and its public importance may perhaps be estimated from the fact that to it has been attributed the influencing of the fate of nations by the limitations of their sea power which it caused. It is not altogether surprising, therefore, that there exists in France and possibly elsewhere in Continental Europe, a "League Against Seasickness." This body, it is reported, proposes to charter a steamer and invite some six hundred physicians to sail from Hamburg, Antwerp and French ports to Lisbon at the time of the International Medical Congress. It is expected that experimental study of the subject will be conducted, and that in this way practical tests of the various methods of treating the condition can be carried out. The projectors should consult naval architects in their selection of the vessel or in the provisions for its outfitting and ballasting. If they secure a sufficiently lively craft, and the Bay of Biscay and other seas are propitious or unpropitious according to the point of view, some valuable subjective and objective testimony may be elicited. The experiment will be worth watching.

MORE ON PURE-FOOD LEGISLATION.

According to the *Chicago Tribune*, it is probable that the Lorimer pure-food bill is to be, or is being, pressed before the Senate this week by its advocates. The same paper says, also, that this bill was partly drawn up by E. N. Eaton, analyst of the pure-food commission of Illinois, who is opposing the Heyburn bill for fear that it would take the inspection and analysis of food products from the hands of state analysts and thus diminish their official functions and importance. If this is the case we do not envy them their responsibility should the Heyburn bill fail to pass. The Lorimer bill is not what

is wanted, and the most obvious cause of its introduction is the desire to defeat the Heyburn measure, which has the indorsement of all the best authorities and of all true well wishers for reform in the matter of food and drug adulteration. The need of a general law is made clear by such facts as are given in the *Chicago Tribune* February 13 concerning the efficiency of the Illinois pure-food commission. According to that paper, it is the practice of the Illinois commission to remit all fines for violations of the state pure-food law, and the manufacturers have come to regard the commission as a thing to be played with, a mere political machine. While similar bodies in some other states are relatively efficient, these facts, if true, in Illinois are sufficient to destroy any dependence on state laws alone. The Lorimer bill, the National Manufacturers' bill and all other similar devices that have been or may be introduced are simply attempts to kill off the measure that is really demanded by all the best interests of the public. As Senator McCumber said in the Senate, their purpose was well stated in the *National Druggist* when the Manufacturers' Association was organized. The heading of its article was "How to Kill Pure-Food Legislation." It is bad enough for the Heyburn bill to find enemies among those who should be its friends, but, after all, opposition from state officials who, by their own inefficiency, furnish an object-lesson for the need of General Government regulation, ought not to be very effective.

LODGE PRACTICE EVIL: A SOLUTION?

The evils of lodge and contract practice are becoming more and more apparent. Medical societies have taken action in various ways, but none thus far taken tends to settle the question without strife. There seems to be at least one way in which this question may be settled, if an agreement to the plan can be brought about. Let the lodges continue to provide medical and surgical attendance for their members, and, if they so desire, let them have their official physicians. Instead, however, of paying the lodge physician a lump sum on the basis of so much per member, which results usually in absurdly small per capita payment, let him be paid the regularly accepted fees for such work as is actually rendered. In case a member desires attendance at the hands of some physician other than the one employed by the lodge, he could, under this plan, call in his own physician, and yet place his lodge at no more expense than though he had been compelled to call in the official lodge physician. We recently called attention to the conflict between the Shasta County (California) Medical Society and a local lodge of "Eagles." There have been some publications in the local press subsequently, and in one of these, emanating from the "Eagles," the statement is made that there have been very few cases of sickness for the lodge physician to attend, and that he has received about \$3.00 for each actual visit, whereas the regular fee for that community is but \$2.50 a visit. If this is the case, the plan here proposed would have resulted in an actual saving to the lodge, while at the same time it would have prevented the existence of strained relations between some of the population of that county and most of its physicians. Would it not be well for medical so-

cieties carefully to consider this idea and the advisability of trying to get the lodges in their various vicinities to adopt it? The co-operative principle, on which lodge and contract practice are based, is growing rather than contracting, and doubtless it will always exist even in its application to medical treatment. It would seem wise, therefore, to endeavor to devise some plan by which its existence will not be a menace to the self-respect of physicians and an influence tending to the reduction of fees—all too small even now.

Medical News

CALIFORNIA.

Scarlet Fever Epidemic.—An epidemic of scarlet fever is reported to be raging in Martinez; 33 cases have been reported, with one death.

Fire in College.—The four-story frame building occupied by the College of Physicians and Surgeons, San Francisco, was damaged by fire January 18, to the extent of \$40,000.

Society Meeting.—Santa Barbara County Medical Society, at its January meeting, elected the following officers: President, Dr. William B. Cunnane; vice-president, Dr. David A. Conrad; secretary, Dr. William T. Barry, and treasurer, Dr. Charles S. Stoddard, all of Santa Barbara.

Prohibits Distribution of Medicine Samples.—The Selma health board is reported to have recommended the passage of an amendment to the present health ordinance making it illegal to give away or to distribute samples of these remedies. The step is said to be taken not so much in the interest of the adult population, but as a matter of protection for children who are liable to be seriously injured by picking up such packages and eating the contents.

Personal.—Dr. Beatrice M. Hinkle has resigned as assistant city physician of San Francisco and has removed to New York City.—Dr. Elliott H. Woolsey, Oakland, has gone to Honolulu for a two months' trip.—Dr. Simon Baruch, New York City, has taken charge of the new Paso Robles bath house.—Dr. Charles W. Bryson has been elected dean, and Dr. I. C. Fisher, vice-dean, of the faculty of the Los Angeles College of Physicians and Surgeons. Dr. Walter S. Johnson has been elected trustee of the college and editorial manager of the *Los Angeles Medical Journal*, vice Dr. Nichols, resigned.

COLORADO.

Officers Re-elected.—At the annual dinner and meeting of the board and faculty of the Denver and Gross Medical College, January 26, Dr. Sherman G. Bonney was re-elected dean of the college and Dr. Robert Levy, secretary.

Pure Water and Power.—Boulder, determined to secure pure water, has purchased several lakes near the crest of the Rocky Mountains which are fed by melted snow. A pipe line will convey the water to Boulder, and the fall will furnish sufficient power for electric light for the city.

Rival Coroners. Dr. R. H. Paxton, who was deposed as coroner by the board of commissioners of Fremont County a few months ago because of alleged non-residence, has brought on proceedings in the county court against Dr. William C. Stevenson, who had been appointed to fill the vacancy. Since Dr. Paxton's removal both physicians have been performing the duties of coroner.

Personal.—Dr. Ella Head has been appointed physician of Greeley.—Dr. Richard W. Corwin, Pueblo, has been elected president of the conference of state charities and corrections, and Dr. Hubert Work, Pueblo, vice-president.

DISTRICT OF COLUMBIA.

Personal.—Dr. Robert F. Tobin has been appointed a member of the medical staff of the Washington Asylum, vice Dr. De Haven Sharp, deceased.

Agree on National Quarantine Bill. The members of the special committee, selected at a caucus of southern senators and representatives, have agreed on a national quarantine bill limiting quarantine measures to yellow fever and appropriate \$500,000 for the work.

Ophthalmologists Regret Burnett's Death.—The Society of Ophthalmologists and Otolologists of Washington, at its regular meeting, held January 19, adopted a preamble and resolutions of sorrow at the death of Dr. Swan M. Burnett, its first president, and of sympathy to his widow and son.

ILLINOIS.

Chicago.

Personal. Dr. John C. Corbus, Mendota, has been re-elected superintendent of the Illinois Eastern Hospital for the Insane, Hospital.—Dr. Gerhard T. Nelson, Morris, while on his way home from a train early January 29, fell and fractured his leg.

Oak Park Hospital Plans.—On February 11 announcement was made that the plans for the Oak Park Hospital have been completed. The site selected is at the corner of Wisconsin Avenue and Monroe Street, with a frontage of 367 feet on Wisconsin and 171 feet on Monroe Street. The building will accommodate 65 patients.

Joint Meeting.—On January 31 the Winnebago County Medical Society and the Central Wisconsin Medical Society held a joint meeting in Rockford, at which the principal subject discussed was the treatment of tuberculosis. In the afternoon the visiting physicians were tendered a banquet at which Dr. Ernest C. Helm, Beloit, presided as toastmaster.

Personal. Dr. John W. Marchillon has returned after two years of study abroad.—Dr. Anthony K. Warner has returned after a ten days' trip to Cuba.—Dr. David J. Doherty, who leaves for the Philippines Islands February 22, is to continue his scientific studies and travel in the islands, and will probably remain away more than a year.—Dr. Albert C. Hammett was seriously injured in a runaway accident, February 1.

Civil-Service Examination.—Examinations for assistant physician in the insane hospitals will be held by the Illinois civil-service commission, February 27, at Cook County Hospital, at the railroad and warehouse commission's rooms, the capitol building at Springfield, and at the city council chamber, East St. Louis. The particulars of the examination were noted in THE JOURNAL of January 27. Applications will be received up to February 23 and should be made to Joseph C. Mason, secretary and chief examiner, Chicago.

Hospitals De Luxe.—James Henry Smith has given \$500,000 to St. Luke's Hospital to be used in the construction of an annex to the institution for pay patients, to be erected on the Michigan Avenue property of the institution. The present hospital building will thereafter, it is said, be devoted entirely to free patients.—The board of managers of the Presbyterian Hospital has already obtained pledges of \$352,000 toward the \$400,000 required for an addition to the institution which, it is claimed, will be the finest and most luxurious hospital in the West.

The Dinner to Baron Takaki. On the evening of February 16, Dr. Nicholas Senn and the Senn Club gave a dinner in honor of Baron K. Takaki, surgeon general, Imperial Japanese Navy. Dr. Fernand Henroffin presided and introduced Dr. Senn, who delivered an eloquent address of welcome to the distinguished guest. Baron Takaki, after a brief response, delivered an address on naval sanitation which dealt chiefly with his researches on beriberi whereby the disease has been practically exterminated from the Japanese navy. When Baron Takaki entered the navy in 1872 three-fourths of the entire sick list was made up of beriberi patients. In the endeavor to overcome this condition Dr. Takaki made a study of the ration of the navy and discovered that it contained too great a proportion of carbohydrates and too little albuminates, and furthermore that the prevalence of beriberi varied directly with the variation of these food constituents. As the result of his investigations, he endeavored to change the constituents of the ration by the issue of barley in place of a part of the rice ration. After many years of strenuous work required by the as strenuous opposition of officers and men of the navy, Takaki gained his point, and with the change in the ration beriberi practically disappeared. Baron Takaki also declared that beriberi can be artificially produced and that it can be positively prevented by diet. In closing his address he gave statistics of the total dead and wounded in the Russo-Japanese war up to Dec. 5, 1905. The total number of dead and wounded was 2,689, 1,392 of whom died instantly and 117 subsequently, leaving a balance of 1,680 wounded. The percentage of death rate was 51 and more than 90 per cent. of the wounded returned to duty.

IOWA.

Variolinum.—The State Board of Health at its last meeting discussed the subject of internal vaccination by means of variolinum. The homeopathic members of the board favored the idea, while the regular and eclectic physicians opposed it. A resolution was passed to ask the present legislature to define vaccination or to legalize the present definition of the State Board of Health.

New Medical Practice Rule.—In accordance with a request from the medical faculty, the board of regents of the State University at its last meeting adopted rules regarding admission to the medical college in conformity with a recent action of the State Board of Medical Examiners providing that no physician will be allowed to take the examination for license to practice in Iowa unless he is a graduate of a school that has a four years' course and that does not give credit for any work done outside of the medical college.

Bills in the Legislature.—The following bills have been introduced in the legislature: A bill for the registration of graduate nurses, and a bill asking for an increased appropriation for the State Board of Health Bacteriologic Laboratory at Iowa City. This laboratory was created by the legislature two years ago and began work in September, 1904. During this time, according to the last report of the director of the laboratory, more than 6,000 examinations have been made. The laboratory is proving very popular with the physicians of the state, and has been instrumental, through early diagnosis, in preventing a number of very probable epidemics of diphtheria and typhoid fever. The entire appropriation asked for will no doubt be granted.

MARYLAND.

Baltimore.

Personal.—Dr. Edward Linden Mellus is in Cairo, Egypt.—Dr. Campbell P. Howard sailed for England, February 3.

Health Report.—Influenza is reported to be very prevalent in Baltimore.—During the week ended February 10 there were 39 deaths from consumption and 36 from pneumonia.

Senior Student Killed.—J. Howard Hughes, a senior medical student at the University of Maryland, was killed by the accidental discharge of his pistol at Jersey City, N. J., February 4.

MASSACHUSETTS.

Damaged by Fire.—The residence of Dr. Robert Burrus, West Newton, was damaged by fire February 8 to the extent of \$12,000.

Anti-Expectoration Law.—Among the bills introduced in the legislature is one providing for a fine of from \$1 to \$10 for every person who expectorates in any public place except in receptacles provided for the purpose. This bill is strongly favored by the Society for the Prevention of Tuberculosis.

Alumni Meet.—The Boston City Hospital Alumni held its annual meeting February 8. Dr. Charles W. Williams, who presided, is succeeded as president of the association by Dr. George A. Leland. Dr. George T. Tuttle was elected vice-president; Dr. William H. Robey, Jr., secretary; Dr. William H. Prescott, treasurer, and Dr. George L. West, member of executive committee.

Hospital Reports.—The number of accident cases treated at the Massachusetts General Hospital in 1905 was 5,459, or 700 more than in 1904. The total of outpatients, however, decreased about 4,000. This is explained by the policy of the hospital of referring back cases to family physicians or institutions where they have been previously regularly treated. The McLean Hospital and the Convalescent Home in Waverly are under the same board of trustees. There was a total deficit for the three institutions for 1905 of \$23,000 as compared with \$21,000 in 1904. It is expected that the new building for women at Waverly, made possible by the bequest of Edward W. Codman and to be called the Codman House, will be ready for occupancy in 1906.

Warren Long in Service. Of the resignation of Dr. John Collins Warren the trustees of the Massachusetts General Hospital say:

In January, 1905, the term of Dr. John Collins Warren came to an end, and for the first time in our history the annual report appears without the well-known name of Warren on its pages. It was voted in accepting the resignation of Dr. Warren that the following minute be placed on our records:

"John C. Warren and James Jackson inspired the efforts that led a general public to establish this hospital in 1814. Dr. Warren remained in the service of the hospital until the year 1853. J. Mason Warren became a member of the surgical staff in 1846 and died in the service of the hospital in 1867. John Collins Warren's name first appeared on the rolls of the hospital in 1865, and with

his resignation then closes for the present this illustrious succession through our whole history, of three men, father, son and grandson, who each in turn have been conspicuous for able, conscientious and devoted service to this great charity. A service which deserves and receives the grateful notice of the trustees, and the thanks of the unnumbered patients who have profited by their skill and devotion.

MINNESOTA.

Ramsey County Election.—Ramsey County Medical Society had its annual meeting January 9, at which Dr. Burnside Foster was elected president; Dr. Paul Cook, vice-president; Dr. Frederick Leavitt, secretary-treasurer, and Dr. Alvah F. Whitman, necrologist.

Two Rooms Endowed.—In consideration of the gift of \$35,000 made by David C. and Frank P. Shepard, to pay off mortgages against St. Luke Hospital, St. Paul, the trustees have invested the donors with an endowment title to two rooms to be designated and known as the "Frances Aurelia Shepard Endowment."

Old Vienna Students Meet.—On February 3 physicians of Minneapolis and St. Paul, who have studied in Vienna, held their first annual banquet. Dr. Jehiel W. Chamberlain, St. Paul, was elected president; Dr. Louis A. Nippert, Minneapolis, vice-president, and Dr. Emil S. Geist, Minneapolis, secretary and treasurer.

Offended at Governor's Action.—It is reported that a majority of the State Board of Medical Examiners is preparing to oppose the action of Governor Johnson in reducing the homeopathic representation on the board from three to two. The governor recently appointed Dr. Oswald Leicht, Winona, a regular, to succeed Dr. William A. Beach, Mankato, a homeopathic practitioner. The governor states that his failure to name a homeopath was an oversight, but that his action is irrevocable.

MISSOURI.

To Stop Improper Advertising.—At the February 10 meeting of the St. Louis Medical Society announcement was made that legislation had been discovered whereby the indecent advertisements of medical firms in the lay press could be suppressed, and the firms successfully prosecuted and driven out of business.

Reform in Control of Municipal Institutions.—At the meeting of the St. Louis Medical Society, February 3, the joint medical council, which consists of delegates from the various medical organizations of the city, presented a plan looking to reform in the system of control and management of the city's hospitals and dispensaries. At the present time the hospitals are under direct control of the health department, the health commissioner having power to appoint all the employees, medical or otherwise, of the various hospitals under the care of the city. There is no provision for a medical staff, either visiting or consulting, the entire medical as well as the executive charge of the hospitals being placed in the hands of a medical superintendent appointed by the mayor. To replace this antiquated system the council has suggested a plan, the principal features of which are as follows: 1. The absolute separation of the health department from the hospital department; 2, the vesting of hospital control in a board of trustees to be elected by the people; 3, the appointment by this board of an executive head for each institution, and 4, the appointment of a medical staff. The plan as presented was endorsed *in toto* by the society and will be brought up for consideration before the other societies represented in the council. It would appear that the profession is a unit in demanding these reforms, which will, however, require amendment of the city charter before they can be made effective.

NEBRASKA.

Training School Opened.—The training school of the City Hospital, Ord, was opened January 1, under the charge of Dr. Chester A. Brink.

Refused License.—The State Board of Health, after a lengthy hearing, adopted the following resolution regarding the application of Dr. Alfred Welsh of Haigler for a license to practice medicine:

Resolved, That a license to Dr. Welsh to practice medicine be denied at this time, and that the matter be referred back to the board of secretaries, and leave granted to amend his application, to be hereafter considered.

Injunction Made Perpetual.—In the suit of Dr. Baker, Madison, against Dr. John R. Montgomery of the same place, in which an injunction was asked on the ground that the defendant had sold his practice to the plaintiff and had agreed not to practice in that field, the district judge decided that a physi-

cian who sells his practice to another may not resume practice in the same field as a competitor of the man to whom he sold, provided that such an understanding existed between them. The judge granted the injunction applied for and made it perpetual.

General Hospital Opened.—The Omaha General Hospital was formally dedicated and opened January 28. The institution will accommodate 100 patients and has in addition accommodations for friends of patients who may wish to remain. The following have been appointed a staff for the ensuing year: Surgeons, Drs. Walter O. Henry and Edwin C. Henry; attending physicians, Drs. Andrew B. Somers, H. Leroy Crummer and John H. Vance; consulting physician, Dr. Benjamin F. Crummer; gynecologists, Drs. Alvo S. Pinto and Frederick J. Wearne; obstetrician, Dr. Alonzo E. Mack; consulting obstetrician, Dr. Joseph C. Moore; oculist and aurist, Dr. Henry L. Burrell; neurologist, Dr. Samuel K. Spalding; dermatologists, Drs. H. Clayton Summey and John W. Hellwig, and gastrologist, Dr. H. L. Akin.

NEW YORK.

To Prevent Marriage of Insane.—A bill has been introduced into the legislature forbidding the marriage of insane, epileptic, imbecile and feeble-minded persons. The bill provides that if thirty days before a marriage of persons known to have been in such a state, they shall file a physician's certificate of cure, the marriage shall not be considered illegal. Another measure makes it a felony for any person of sound mind to intermarry or live with such a person or aid in such a marriage. The punishment is ten years' imprisonment or \$1,000 fine, or both.

Violations of Pure-Food Law.—Papers have been served on two prominent grocers of Schenectady in civil actions instituted by the so-called pure-food law. Eight more actions against other grocers will be instituted within a few days. The penalty is \$100 for each offense. The action was brought by a special attorney assigned to the state department of agriculture. Last spring the state commissioner of agriculture sent inspectors all over the state to secure samples of food-stuffs for analysis. The results of these analyses were appalling. Eight hundred cases of violation of the pure-food law were sent to the attorney general, who sent them to the special attorneys appointed to the several counties. Owing to the deplorable conditions found, it is understood that sweeping amendments to the pure-food laws are to be submitted by the department of agriculture to the legislature for immediate adoption. Under existing laws it is impossible to reach the real offenders, many of whom are outside the state.

New York City.

New Health Department Building.—Health Commissioner Darlington formally opened the new laboratory building of the department February 9.

Microscopes for Columbia.—An equipment of microscopes for the department of physiology has been presented to this institution by Dr. David L. Haight, a graduate of the medical school in 1864.

Reception to Baron Takaki.—After the regular meeting of the New York Academy of Medicine on February 15 a reception to the baron was held, at which he made some remarks on medical schools in Japan.

Harvey Society Lecture.—The ninth lecture in the Harvey Society course will be delivered by Prof. T. H. Morgan, February 17, on "The Extent and Limitations of the Power to Regenerate in Man and Other Vertebrates."

Dinner for Hospital.—The committee which was appointed at the dinner for the Manhattan Eye and Ear Hospital last year to furnish a dinner in 1906 has arranged to give this dinner at the University Club, February 20.

Low Death Rate.—The death rate for the week ended February 3 was the lowest on record for the corresponding week in any year since the records have been kept, being equivalent to an annual rate of 18.1 per 1,000. Last year the rate for the corresponding week was 19.53.

Remodeled Willard Parker Hospital Opened. This hospital was reopened to the inspection of physicians and the public February 9. Among the many new features of the building are the sun parlors on every floor and the thoroughly equipped wards for treating contagious diseases.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended February 3, 1,189 cases of measles, with 52 deaths; 378 cases of diphtheria, with 39 deaths; 343 cases of tuberculosis, with 178 deaths; 208 cases of scarlet

fever, with 7 deaths; 41 cases of typhoid fever, with 3 deaths; 28 cases of cerebrospinal meningitis, with 17 deaths, and 180 cases of variella, a total of 2,667 cases, with 296 deaths.
